EXPERIMENT STATION RECORD

Volume XXV, 1911
U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus.

Weather Bureau—Willis L. Moore, Chief.
Bureau of Plant Industry—B. T. Galloway, Chief.
Forest Service—H. S. Graves, Forester.
Bureau of Soils—Milton Whitney, Chief.
Bureau of Statistics—V. H. Olmsted, Statistician.
Bureau of Entomology—L. O. Howard, Entomologist.
Bureau of Biological Survey—H. W. Henshaw, Chief.
Office of Public Roads—L. W. Page, Director.

Office of Experiment Stations—A. C. True, Director.

THE AGRICULTURAL EXPERIMENT STATIONS.

ILLUSTRATION.

Fig. 1. Diagrammatic vertical section of potometer used in studying transpiration in corn .................................................... 832
EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., Assistant Director.
Assistant Editor: H. L. Knight.

EDITORIAL DEPARTMENTS.

Agricultural Chemistry and Agrotechny—L. W. Fetzer, Ph. D., M. D.
Meteorology, Soils, and Fertilizers—W. H. Beal
W. H. Evans, Ph. D., H. W. Tillman.
Agricultural Botany, Bacteriology, Vegetable Pathology—W. H. Evans, Ph. D.
W. H. Long.
Field Crops—L. I. Schulte.
Horticulture and Forestry—E. J. Glasson.
Foods and Human Nutrition—C. F. Langworthy, Ph. D.
Zootechny, Dairying, and Dairy Farming—E. W. Morse.
Economic Zoology and Entomology—W. A. Hooker.
Veterinary Medicine—L. W. Fetzer.
Rural Engineering—B. B. Hare.
Rural Economics—D. J. Crosby.
Agricultural Education—C. H. Lane.

CONTENTS OF VOL. XXV, NO. 1.

Editorial notes:

The miscellaneous character of station publications.......................... 1
The International Institute of Agriculture and its publications.............. 5
Additional abstract numbers of Experiment Station Record................... 8
Recent work in agricultural science........................................... 9
Notes.................................................................................. 96

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

The biological reactions of the vegetable proteins, Wells and Osborne........ 9
The aporhegmas, Ackermann and Kutscher......................................... 9
Collecting and measuring the gases evolved during fermentation, Harden et al. 9
The precipitation of the sulphate ion as barium sulphate, Ruppin............. 9
A volumetric method of determining iodid, Bray and MacKay.................. 10
A note in regard to the Kjeldahl method for nitrogen, Harrison and Self..... 10
A new method for estimating phosphoric acid, Martin.......................... 10
Titrametric determination of citrate-soluble phosphoric acid, Wuyts.......... 10
Citrate solubility of phosphoric acid in basic slag, Flack.................... 11
Estimating the phosphoric acid in soils and crops, Kaserer and Greisenegger. 11
Determining phosphoric acid by Neumann's method, Krasser.................. 11
Some methods of analyses for soil investigations, Vesterberg................. 11
Methods of soil analysis employed at the Passerocean Sugar Station [Java].... 12
A biochemical reaction for pollution in water supplies, Sellards and Bartow.. 12
Some considerations on colorimetry, and a new colorimeter, Roberts......... 12
Method for the analysis of fat, David....................................... 12
In regard to the Kumagawa-Suto method for fat, Shimidzu ................................................ 12
Determination of fat in foods, Polenske .......................................................... 12
About banana flour and its microscopic examination, Hanousek .................................................. 12
Determination of solids in vinegar, Mohan .......................................................... 12
Estimation of phosphoric acid in ciders and vinegars, Hashrouck ................................................. 13
Honey fermentation and the chemical composition of honey, Nussbaumer ........................................ 13
Identification test for caramel, Lichthardt .......................................................... 13
Saffron and its adulteration, Collin ................................................................. 13
Distilled liquors: Whisky, brandy, and gin, Holm describing ................................................. 13
The bitter acid content of Hungarian hops, Bird .................................................. 13
The sources of error in the Folin method for creatinin, Taylor .................................................. 13
A modified guaiac test with sodium peroxid, Bardach and Silberstein ................................. 13
The chemical processes involved in the coagulation of milk by rennet, Bang .................................... 13
Contribution to our knowledge of milk catalase, Spindler .................................................. 14
Estimation of catalase in milk, von Heygendorff and Meurer ................................................. 14
A method for the estimation of citric acid in milk, Desmoulière ............................................ 15
A method for the estimation of reducing sugars, Benedict .................................................. 15
Invert sugar and its importance for seed beet polarization, Stephani ........................................ 16
Examining raw materials and products of sugar industry, Frühling ......................................... 16
The determination of nicotin in nicoin solutions and tobacco extracts, Chapin ......................... 16
Commercial turpentine: Their quality and examination, Veitch and Donk ..................................... 16

MEETEOROLOGY—WATER.

The atmosphere: Its characteristics and dynamics, Cordeiro ................................................. 17
Nitrates in the air of southern regions, Müntz and Laine .................................................. 17
The influence of the moon on plant growth, Flammarion .................................................. 17
Monthly Weather Review ......................................................................................... 18
Meteoro logical observations ......................................................................................... 18
Note on silt carried by the Nile during floods of 1908 and 1910, Hughes ................................. 18
The artesian water supply of eastern Florida, Sellards and Gunter ........................................ 18
Sterilization of water on a large scale by means of ultraviolet rays ........................................ 19

SOILS—FERTILIZERS.

The gumbo soils of Iowa, Stevenson and Barker .......................................................... 19
The management of heavy clay soils, Whitson and Delwiche ................................................. 19
The improvement of sandy soils, Whitson and Sievers .................................................. 19
The development of marsh soils, Whitson and Sievers .................................................. 20
Contribution to the theory of soil drainage, Krüger .................................................. 20
Lysimeter investigations, 1910, Krüger ........................................................................ 21
Investigation on the adequacy of nutrients in forest soil, Vater ............................................. 21
Absorptive capacity of soils from physico-chemical standpoint, Pratolongo .................................. 21
Tests of an osmotic theory of plant distribution, Gola .................................................. 21
Chemical analysis, a means of determining soil structure, Puhrner ........................................ 22
The formation and properties of humus substances, Ehrenberg ........................................ 22
The question of the study of humus substances, Blacher ................................................ 22
Escape of ammonia from manure during hauling, Liecht and Ritter ..................................... 22
The importance of peat for the manufacture of nitrogenous fertilizers, Schorr ................. 22
Problems in peat filler production, Hoff ........................................................................ 22
The world movement of nitrogen in 1910, Bertrand .................................................. 23
Nitrate of soda ............................................................................................................. 23
Nitrate of soda in a Texas county, Phillips ........................................................................ 23
Ammonia production in 1910, McIlvray ........................................................................ 23
Sulphate of ammonia ................................................................................................ 23
Recent progress in the fixation of atmospheric nitrogen, Kershaw ...................................... 23
The fixation of the nitrogen of the air, Bachmann .................................................. 24
The knowledge of lime nitrogen, Caro ........................................................................ 24
Potash salts: Their uses and occurrence in the United States, Phalen ..................................... 24
The potash industry and the American farmer, Reeve .................................................. 24
Potash for over 600,000 years ....................................................................................... 24
Other potash deposits ................................................................................................ 24
Phonolite as a fertilizer, Popp ..................................................................................... 24
Feldspar as a source of potash, Machalske ........................................................................ 24
Florida phosphate industry in 1919, Memminger .................................................. 24
AGRICULTURAL BOTANY.

Action of anodic and cathodic liquids on germination, Micheels. 25
The action of an alternating current on germination, Micheels and De Heen. 26
The effect of salts on the respiration of plants, Reinhard. 26
The function of hormones in stimulating enzymic change, Armstrong. 26
Investigations regarding the phloem and food conduction in plants, Agrellus. 27
Phototaxis, assimilation, and growth, Dangeard. 27
Metabolism and translocation in young conifers, Bauer. 27
The morphology of leaf fall, Lee. 27
The glucosid of pear leaves and its rôle, Bourquelot and Fichtenholz. 27
The behavior of tannin in persimmons, with some notes on ripening, Lloyd. 28
The effect of the frosts of the winter of 1908-9 on vegetation, Chittenden. 28
Plant acclimatization in southern Arizona, Thornber. 28
Weeds in relation to the soils on which they grow, Brenchley. 28
Physiological aspects of fertilization and hybridization in ferns, Hoyt. 29
Do ferns hybridize? Benedict. 29
Naudin and Mendel's law relative to the segregation of hybrids, Blairingham. 29
The mutation theory, I1, De Vries, trans. by Farmer and Darbishire. 29
Inheritance of the yellow tinge in sweet pea coloring, Thoday. 30
A spineless mutation of Gynara cardunculus, Trabut. 30
International catalogue of scientific literature. M—Botany. 30

FIELD CROPS.

A report of seven years' investigation of dry farming methods, Merrill. 30
Dry farming: A system of agriculture under a low rainfall, Widtsoe. 31
References on plant breeding, Fruwirth. 31
The importance of the origin and improvement of grasses and clovers, Witte. 32
Indigenous and acclimated forage crops of Argentina, I, Girola. 32
[Experiments with field crops, Barbados 1909-10], Roxell. 32
[Experiments with cotton and sugar cane], Corrie and Mitchell. 32
[Manorial experiments with potatoes and turnips], Macpherson. 32
A successful alfalfa and truck farm in southeastern Ohio, Lloyd. 32
The phosphoric acid and potash requirements of meadows, Lièchti. 33
Field trials on the liming of meadow land, 1906-1909, Milburn and Gaut. 33
Trials with grass mixtures in 3-year meadows, 1883-1902, Nielsen and Lindhard. 33
Yields of grasses of different species, 1879-1907, Nielsen and Lindhard. 33
Seeding laws and permanent pastures. 33
Tests of Chile salt peter under small grains, Janco. 33
Some data on work with buckwheat, Althausen. 33
Schoblar clover, Trabut. 34
Fermentation in the hay rick, Wale and Keable. 34
Corn secrets, Heldcn. 34
Corn growing in Louisiana, Roy. 34
The chemical composition of the different parts of the corn plant, Weiser. 34
Uniform distribution of seed in planting compared with a varied distribution. 34
Cotton-growing experiments in Mexico, Miller. 34
Cotton crop of Peru, Miller. 34
Notes on hops, Salmon. 34
The hop garden. 35
Trials with mangel seeds from large and small roots, Helweg. 35
Factors influencing the yield of oats, Demarce. 35
Field trials with oat varieties, 1901-1908, Hansen and Mortensen. 35
Tenth year's trials with root crops, Helweg. 35
The newer fertilizer tests with beet seedlings, Sempolowski. 35
The sugar beet industry in Nevada, Knight. 36
[Variety tests and analyses of sugar cane], Corrie. 36
The composition of wheat, Ames. 36
Improvement in the wheat from Central Provinces, Evans and Humphries. 36
An examination of the seed supply of the Broach District, Mehta. 36

Note.—The price of *Experiment Station Record* is $1 per volume, and two volumes are issued annually. It may be purchased from the Superintendent of Documents, Washington, D. C., to whom all remittances should be made. The publications of the State experiment stations are distributed from the stations and not from the Department.
In the elaboration of the organization of the agricultural colleges, which is now proceeding rapidly because of the great expansion of their work, the experiment station is generally regarded as the research division, as distinguished from the teaching and extension divisions. This fact is, however, obscured in the eyes of the public because of the great variety of publications which are being issued by the stations.

The miscellaneous character of these publications can not be said to have diminished as the stations have grown in experience and in the attempt to organize and differentiate their work. The number of publications has greatly increased, but in a majority of cases this increase is not made up of accounts of the station’s activity as a research institution. It consists largely in the number of popular and informational bulletins and circulars, which relate to the extension department rather than to the experiment station proper. These are merged in the general station series in a manner which often gives a wrong impression.

There have been several successful efforts to start separate technical series which report the station’s investigations in more scientific language and detail. This step is commendable in excluding the more technical accounts of station work from the general mailing list, and bringing such accounts to the notice of the persons for whom they are especially prepared. Such a classification is highly desirable if the miscellaneous character of the station publications is to continue, for not the least important phase of this subject is the influence the arrangement has on scientific readers.

The heterogeneous mixture of popular, semipopular, and technical articles, based in part on station work and in part on general sources of information, reports of inspection work and police regulations, announcements of college courses, nature-study publications for teachers and pupils, serves to obscure largely the bulletin of technical value. It makes it difficult for the station publications to secure the interest of and recognition from people interested in scientific and technical studies, because of the large mass of material under which
it is buried, material which is useful in itself when distributed to the proper audience, but which serves to convey a wrong impression to the public mind and to the man of science as to the field and the work of the experiment station.

The annual report was formerly a place for technical papers of permanent value, as well as a general review of the station's activities for the year. This has come now to be very largely a purely administrative and fiscal report, brief and very general, often without even an enumeration of the projects or lines of work conducted during the year. As such it has ceased to have much interest or value as a record of progress. The coming of the Adams fund and the large amount of investigation which has grown out of it, has not as yet had a very noticeable influence on these reports or on the station publications as a whole. The Adams Act is supplying results of scientific interest and of practical application, and in a way it is furnishing a higher conception of experiment station work as a whole, but its influence on the publications has thus far been restricted and has been largely overshadowed by the demand for the more popular class.

The actual condition with reference to the character of the publications sent out by the experiment stations is shown by an examination of the records for the six months ended with April 1 of this year. It is found that out of 276 publications issued during that period 104 are records of the experimental work of the stations. In other words, only two-fifths of the total number of publications are of that description. Seventeen of these record scientific investigations such as would be appropriate under the Adams Act; 87 contain accounts of field experiments, miscellaneous studies in entomology, plant pathology, and veterinary medicine, and minor laboratory work in different departments.

Ninety publications, or about one-third of the total number, are miscellaneous popular publications covering a wide variety of subjects. Eleven of these are résumés of more technical publications recording experimental work, and some others contain more or less definite references to such work, but most of them are properly described as compilations of information from various, and usually indeterminate, sources. More than half of them are brief circulars, the relation of which to experimental work is quite remote.

The remaining publications, nearly one-third of the whole number, are of a formal and routine character. Forty-four are called forth by the inspection service, and there seems to be a tendency to multiply publications of this kind by dividing the reports of inspection work into small sections. This is probably largely due to the growing variety of inspection work, the results of which are of in-
terest to different classes of readers, and the desire to get the reports of the service out promptly. Eight bulletins recording routine meteorological observations are in this list. There are also thirty annual reports, which with few exceptions are wholly of an administrative character.

Without knowing in detail the method of distribution of the station publications, it is impracticable to judge accurately of the effect of the issuance of so many kinds of publications. It is, however, probable that the widest circulation is given to the more popular publications. Since these for the most part do not definitely record experimental work, it would naturally follow that the general impression to be created would be that the stations are agencies for the general diffusion of agricultural information. There is much reason for believing that the public generally now consider the stations in this light.

This impression must be deepened by the miscellaneous character of the subjects treated in the compiled publications. A few examples of the titles of these publications will illustrate this point: Opportunities for profitable farming, Orchard practice, Poultry raising, Farm butter-making, Seed testing, The scheme of distribution of seeds and plants, A competitive corn test, Iron cow stall, Selecting and judging corn, Distribution of licensed stallions (in a certain region), Headache remedies, Lighting of farm homes, Tree growing at public schools, Experiments with plants and soils in laboratory, garden, and field (50 school exercises).

In the last case the term “experiments” is used in that loose and unfortunate meaning, as applied to the demonstrations or trials of well-known facts and principles by school children. The bad effects of such terminology is widely seen even in our higher institutions of learning and among experiment station men. It seems difficult under such conditions to establish correct standards for real experimental work.

The franking privilege possessed by the experiment stations, and thus far denied to the other divisions of the agricultural colleges, undoubtedly accounts for the inclusion of some publications in the station list. The performance of extension work by some stations under State laws has naturally led to their issuing extension publications.

One serious feature of this habit of issuing compilations which our stations have acquired is the great amount of time and energy thus diverted from experimental work. In this way not only is the amount of experimental work greatly diminished but the enthusiasm of the worker for experimental effort is often impaired. When once the easy path to public favor through the compiled bulletin has been
trod it seems difficult for many men to pin themselves down again to painstaking and serious investigation of new problems.

The Office of Experiment Stations has ruled out the purely information bulletin as far as the use of the Federal funds is concerned—not that there may be no popular accounts of the station work and results, but rather that the popular bulletins of the stations shall be confined to such accounts, and the compiled bulletin or circular which makes no reference to the station issuing it and bears no relation to its work shall be segregated as far as expense is concerned from the legitimate field of the station. It has urged, furthermore, that in these popular accounts of the station work the station should be credited with having furnished the basis for the discussion, by definite reference to its experiments, in order that the account may not appear to be drawn from general sources of information.

Some little difficulty has been experienced in securing the recognition of these general principles, which should leave the station man free for his investigations and experiments in proportion to his salary from station funds, and should present in popular as well as technical accounts of experimental work the evidence on which the discussion rests, crediting the station with its contribution to the subject. In practice the station men continue to be called on for miscellaneous bulletins bearing no particular relation to their work, the preparation of which is usually a hardship and is an unfortunate interruption. Why should a station horticulturist, for example, who is charged with a large and exacting piece of research which is supposed to require most of his time, be expected to issue a comprehensive bulletin on the apple industry of his State, a résumé of general information on the methods of culture and care of an apple orchard, and similar matters; or a dairyman who is at the head of an experimental department devote his time to describing butter making on the farm as his only outgiving of the year? The limited time which such men have for experimental work which will add new facts or applications and be of permanent value is far too precious.

If our stations generally are ever to become strong experimental and research agencies and put their work on a truly scientific basis, they must be willing to limit the field of their activity in both work and publication. When we look away from the station publications to see what is actually going on at the stations, we are encouraged to find an increasing body of men devoting themselves as far as they are permitted to definite experimental work, a considerable portion of which is of a relatively high scientific character.

It will be a happy day for the American stations when the extension departments now being organized in the agricultural colleges
take over fully the bureau of information work and publications and leave the station workers free to pursue their more legitimate functions.

Among the results attending the third session of the general assembly of the International Institute of Agriculture, which was held in Rome May 14-20, has been the bringing to the attention of the public the substantial progress which is being achieved in the development of this enterprise. Much of the interval which has elapsed since the initial conference in 1905 has of necessity been occupied in obtaining the cooperation and support of the forty-eight nations which have signed the convention establishing it, and in solving the relatively complex problems incident to the organization of so novel and extensive an undertaking. With the passing of the pioneer stage, however, the work of the Institute has been assuming more tangible form, and the last two years in particular have been noteworthy for the inauguration of several promising lines of work, among these the establishment of a number of serial publications of interest to scientific workers in agriculture.

It will be recalled by those familiar with the plan of organization of the Institute that the general assembly is its governing body. Its duties are to vote the budget of the Institute, to review and approve the work of the "permanent committee," which is the executive body, and to authorize any changes contemplated in the plan and methods of work.

The assembly is a delegate body to which special representatives are sent by the adhering countries. In the decision of questions the various nations are on an equal footing, each having a single vote. A nation may, however, send as many delegates as it desires, and in most instances several representatives are appointed. In consequence the meetings are the occasion of bringing together a considerable body of men interested in agriculture from all over the world, and the social features which attend the gatherings serve to emphasize in a striking way the international aspect of this union of the world's forces in the promotion of the greatest of international industries.

As is well known, credit for the conception of the general plan of the Institute belongs to an American, Mr. David Lubin, of California, who has remained the representative of this country on the permanent committee throughout. The delegates to the recent general assembly included Hon. David J. Foster, recent chairman of the Committee on Foreign Affairs of the House of Representatives; Hon. Charles F. Scott, formerly chairman of the House Committee on Agriculture; Director E. Dana Durand, of the Bureau of the

For a detailed account of the formation and plan of organization of the Institute, see a previous note (E. S. R., 10, pp. 500-503).
Census; Mr. Victor H. Olmsted, Chief of the Bureau of Statistics of this Department; and Mr. Edgar R. Champlin, of Boston.

Aside from the administrative reports upon organization, finances, and the routine work of the various bureaus, a number of special questions of international importance were presented to the assembly for discussion. The results of an inquiry as to measures in operation in the various adhering countries for the protection of birds were summarized by the permanent delegate of Hungary, E. de Miklós. The feasibility of an international meteorological service was discussed by the French delegate, Louis Dop. Prof. G. Cuboni, delegate of Ethiopia, described measures to be taken to establish an effective cooperation between nations in the combating of plant diseases, and suggestions were made as to the measures desirable to check the spread of dodder. The utility of an international agreement as to insurance against hail was discussed by the Norwegian delegate, G. Fjelstad, and the Austrian delegate, V. de Pozzi.

The subject of agricultural statistics was, as usual, a leading topic of discussion, as this is one of the principal duties specifically intrusted to the Institute. Dr. T. Müller, delegate of Germany, reported on those for crop production; the Russian delegate, G. Zabiello, on prices and similar commercial aspects; the Belgian delegate, O. Bolle, on the organization of an international service of foreign correspondence; and the Austrian delegate on statistics of agricultural and cooperative societies. A phase of statistical work which received particular consideration was the method of expression of statistical reports as to crop conditions. It has been learned that the method in vogue in the Bureau of Statistics of this Department in which the conditions are expressed in percentages was adopted as the official method of the Institute.

The compilation of agricultural statistics has from the start received particular attention from the Institute. Among its earliest publications were volumes entitled L'organisation des Services de Statistique Agricole dans les Divers Pays, L'organisation des Services de Statistique en Suède, and Statistique des superficies Cultivées, de la Production Végétale, et du Bétail dans les Pays Adhérents. Since January, 1910, there has also been published a monthly Bulletin of Agricultural Statistics, issued in English, French, German, Spanish, and Italian editions, and briefly summarizing the prevailing crop conditions throughout the world.

Another duty formally assigned to the Institute is to "study questions concerning agricultural cooperation, insurance, and credit in all their forms, collect and publish information which might be useful in the various countries in the organization of agricultural cooperative insurance and credit institutions, [and] state the wages of
EDITORIAL.

farm laborers." The carrying out of this work has been delegated to a bureau under the direction of Prof. Giovanni Lorenzoni, and beginning with September 30, 1910, a monthly Bulletin of the Bureau of Economic and Social Intelligence has been issued dealing with these subjects. The initial numbers have dealt especially with the present status of agricultural cooperation and the wages of farm laborers, this presentation being preliminary to more detailed studies. The publication is printed in French, and for the present in English editions as well, and each number contains about 400 pages of material, arranged on a geographical basis and summarizing available data, as well as monographs on certain phases of the subject, news notes as to the progress of agricultural cooperation, and other items of related interest. It is announced that subsequently it is hoped through direct collaboration with the various countries to arrange for the publication of original material as well.

A third serial publication is the Bulletin Bibliographique Hebdomadaire, which is now in its second volume. This consists of two portions, the first a classified list of the accessions received by the library of the Institute during the week under review, thus corresponding in a general way to the Monthly Bulletin of the Library issued by this Department, and the second a similarly classified list of articles of general agricultural interest which have appeared in the serial publications received. Brief notes as to the scope of these articles accompany the reference to them in some cases.

The remaining serial publication of the Institute, Bulletin of the Bureau of Agricultural Intelligence and of Plant Diseases, has the announced purpose to "review without delay the scientific and technical, and in part the legislative, literature of agriculture and the allied industries," and to furnish "a periodical summary of the agricultural literature of the world." It is published monthly, each number reviewing material received for the month preceding, and thus far each number has contained about 200 pages. At present both English and French editions are issued.

The supervision of this publication is intrusted to two directors, Prof. Italo Giglioli and Dr. Jules M. Saulnier. They are assisted by a corps of 11 abstractors and several translators.

Inasmuch as the statistical and economic phases of agriculture are provided for in the Institute publications already described, it is the announced intention to restrict this Bulletin to "the domain of the physical, chemical, biological, and technical conditions which govern farm and forest." In the numbers which have thus far appeared, however, while the more scientific phases have been by no means disregarded, there is still an evident preference in the selection of material for review for articles of a popular nature and of immediate
practical interest, and a tendency to give considerable space to the economic significance of the data presented. In this respect the point of view of the Bulletin differs from that of Experiment Station Record, in which the aim has been rather to present the new scientific truths which have been discovered, with reference to their bearing on the fundamental principles of the agricultural industry. Whereas the Record is designed for the use of the agricultural investigator and teacher rather than directly by the farmer, the treatment in the Bulletin is such as to afford assistance to both classes of readers.

With the large and constantly increasing body of agricultural workers, scattered through so many lands and presenting their results in so many tongues and so diverse mediums, the establishment of agencies for the assembling, preservation, and dissemination of the results of the vast fund of agricultural knowledge which is accumulating becomes of increasing importance with every year. The oblivion in which the work of Mendel was buried for many years may be cited as a well-known instance of what has doubtless not infrequently befallen important researches reported in obscure publications and remaining unknown to the average investigator. By reason of its international organization and other facilities at its disposal the International Institute of Agriculture would seem to have before it unusual opportunities to act as a clearing house of agricultural statistics and literature. Its activities along these lines will be most heartily welcomed by the workers in agricultural science of the world, to whom, if it is accorded the support necessary, it should be able to render valuable service.

To meet the recent increase in volume of the literature reviewed in Experiment Station Record, arrangements have been made for an additional abstract number in each volume, beginning with the current one. In this way each volume will hereafter contain nine numbers and an index. It is hoped that the extension may make it possible to keep the published reviews quite closely up to date.
RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

The biological reactions of the vegetable proteins, H. G. WELLS and T. B. OSBORNE (Jour. Infec. Diseases, 8 (1911), No. 1, pp. 66-124).—These experiments were performed with the globulin obtained from the castor bean, flax seed, and squash seed, with edestin from the hemp seed, excelsin from the Brazil nut, proteins from the coconut, legumin from the vetch, legumin and vicilin from the pea, vinun from the cowpea, glycinin from the soy bean, gliadin from wheat and rye flour, hordein from barley, and zein from maize. All of these were found to produce typical anaphylaxis in sensitized animals, the condition possessing all of the characteristics which are present when anaphylaxis is produced with serum or other animal substances containing soluble proteins.

It was found that considerable differences in toxicity were produced by the various proteins. “The most toxic proteins, as measured by the frequency of severe and fatal reactions, were the globulin of the squash seed, vinun, excelsin, and castor-bean globulin, which usually caused death when given in 0.1 gm. doses to properly sensitized animals. Edestin caused the least severe reactions of any of the proteins, while hordein and glycinin seldom caused fatal reactions; nevertheless, the minimum sensitizing and intoxicating doses of edestin and squash-seed globulin are essentially the same.”

The experiments showed, furthermore, that where continuous feeding was done with the proteins, the guinea pigs became immune to the proteins and could not be sensitized to them. There was a marked specificty shown within certain limits by the proteins, and a close similarity, if not identity, of the legumin of the pea and vetch and the close relation to the vicilin of the pea was shown by the interaction of these proteins. The probable identity of the gliadins from wheat and rye, or at least their near relation, was also established. “In some instances doubtful results were obtained, for example with some guinea pigs castor-bean globulin and flax-seed globulin interacted strongly, while with others similarly treated no reactions were obtained.”

The aporrhegmas, D. ACKERMANN and F. KUTSCHER (Ztschr. Physiol. Chem., 69 (1910), No. 3-4, pp. 265-272; abs. in Chem. Abs., 5 (1911), No. 6, p. 1112).—The authors propose the name “aporrhegma” to designate all the fragments of amino acids which arise during the physiological cycle of plants or animals. They believe that the cleavage of amino acids in the tissues of higher plants and animals goes on in the same manner, and has the same intermediary products as are involved in the biochemical processes of the putrefactive organisms. The paper also discusses methylated aporrhegmas, the significance of methylation, the origin and distribution of betains in plants, etc.

Apparatus for collecting and measuring the gases evolved during fermentation, A. HARDEN, J. THOMPSON, and W. J. YOUNG (Bio-Chem. Jour., 5 (1910), No. 5, pp. 230-235, figs. 2).—The apparatus is described and illustrated.

The precipitation of the sulphate ion as barium sulphate, E. RUPPIN (Chem. Ztg., 34 (1910), No. 135, p. 1201).—The author proposes the following
method which is claimed to have definite advantages in regard to accuracy and time but cannot be used for solutions containing heavy metals.

The dilute, slightly acid (HCl) solution containing the sulphate ion is brought to active boiling, and to it is added an excess of barium chloride (200 gm. of water-free salt in 1 liter), corresponding to 50 per cent of the sulphate present. The mixture is allowed to stand until the next day, the supernatant fluid poured off through a filter, and the filtrate thrown away. The residue is then boiled for ¾ hour with 125 cc. water which has been slightly acidified with nitric acid, and allowed to settle. The supernatant fluid is passed through the original filter and the residue repeatedly subjected to the same treatment until the precipitate is free of chlorin.

The wash waters in each instance are reserved, and after the completion of the process the filter is punctured and the portion of the precipitate on the filter is washed into the beaker containing them. The wash waters are then concentrated to a bulk of 200 cc., and to them is added 2 cc. of a saturated barium nitrate solution, cooled, and the resulting precipitate allowed to settle ¾ hour. After this the precipitate is brought on the filter and washed, the major precipitate is added, and the whole dried at 100° C. The precipitate is then separated from the filter and both filters employed in the process are incinerated in a porcelain crucible. The ash is added to the precipitate, heated with a small flame, cooled, and weighed.

A volumetric method of determining iodid in the presence of chlorid, bromid, or free iodin, W. C. Bray and G. M. J. Mackay (Jour. Amer. Chem. Soc., 32 (1910), No. 10, pp. 1193-1205).—"In this article a method of determining iodid in aqueous solution is described, which depends upon the oxidation of the iodid... by permangante, the removal of the liberated iodin by carbon tetrachlorid, and the titration of this iodin with a standard sodium thiosulphate solution."

A note in regard to the Kjeldahl method for determining nitrogen, E. F. Harrison and P. A. W. Self (Pharm. Jour. [London], 4, ser., 31 (1910), No. 2437, p. 3; abs. in Chem. Ztg., 34 (1910), No. 100, Repert., p. 409).—The authors draw attention to the fact that when distilling off the digested fluid a portion of the alkaline fluid is carried over with the vapors into the distillate, thus bringing an error in the final results.

A new method for estimating phosphoric acid, G. F. W. Martin (Abs. in Ztschr. Angew. Chem., 24 (1911), No. 4, p. 173).—The phosphoric acid is precipitated as ammonium phosphomolybdate. After washing with distilled water the precipitate is dissolved in an excess of potassium hydrate and the ammonium contained in the mixture distilled over into a measured amount of normal acid (102 parts of ammonium=142 parts of phosphoric acid).

Titrametric determination of citrate-soluble phosphoric acid, L. Wuyts (Ann. Pharm., 1910, p. 337; abs. in Ann. Pestif., 4 (1911), No. 27, p. 36).—The method is as follows:

To 10 cc. of a 2 per cent citrate-phosphate solution add a few drops of hydrochloric acid, evaporate in a small porcelain dish, add 3 or 4 drops of nitric acid and a few cubic centimeters of water. Then add 10 cc. of strong nitric acid (specific gravity 1.4), 15 cc. of ammonia, boil for from 2 to 3 minutes, cool, add 25 cc. of ammonium molybdate, and stir with a glass rod. Decant on the filter with cold water; 5 to 6 washings are usually sufficient. Dissolve the precipitate in potassium hydrate solution, controlling this with phenolphthalein, add 50 cc. of water, and titrate back with a normal solution of sulphuric acid. The number of cubic centimeters of potassium hydrate solution utilized directly represents the percentage of phosphoric acid present.
Citrate-solubility of phosphoric oxide in basic slag, E. V. FLACK (Chem. News, 102 (1910), No. 2657, pp. 224, 222, abs. in Analyst, 36 (1911), No. 418, p. 32).—The author shows that, as is well recognized, there is a wide difference between the proportion of phosphoric acid dissolved from basic slag by Petermann's neutral ammonium citrate solution and the proportion dissolved by 2 per cent citric acid solution.

"The author points out that, in analyzing the citric acid solution of the slag, if the phosphoric acid be determined by 'direct' precipitation with magnesia mixture in presence of ammonium citrate, reliable results can not be obtained unless the silica is first removed by evaporation of the solution to dryness with strong hydrochloric acid. Unless this precaution is observed, the percentage of soluble phosphoric acid indicated is, in his experience, on the average about 0.5 per cent too high."

Estimating the phosphoric acid in soils and crops, H. KASERER and I. K. GREISENNEGER (Ztschr. Landw. Versuchsg. Österr., 13 (1910), No. 10, pp. 795-802; abs. in Chem. Zentralbl., 1910, II, No. 21, p. 1631).—The authors utilized Neumann's method (E. S. R., 12, p. 21; 20, p. 111), with certain modifications, for estimating the phosphoric acid in plants and soils, as follows:

From 2 to 3 gm. of the comparatively dry substance is burned with sulphuric acid, 1 drop of mercury, and 1 gm. of potassium sulphate. When the process is completed the mixture is transferred to a 165 cc. flask, filled to the mark with water, allowed to stand over night to let the silicic oxide settle, and then filtered. To 150 cc. of the filtrate 50 cc. of ammonium nitrate (500 gm. ammonium nitrate in a liter of solution) is added, the solution heated to from 80 to 90° C., 40 cc. of 10 per cent ammonium molybdate solution (100 gm. of ammonium molybdate in 1 liter) added, and the mixture allowed to cool. The solution is filtered through a Gooch crucible containing an asbestos filter (at least 15 minutes and not over 3 hours after precipitation and cooling), washed with water and alcohol, and the precipitate washed back into the beaker glass and dissolved with one-fourth-normal sodium hydrate, using phenolphthalein as the indicator. The solution is then boiled for 15 minutes and the excess of alkali titrated back with acid. One cc. of one-fourth-normal sodium hydrate solution = 0.634 gm. of P2O5.

Soils (50-gm. samples) are decomposed with 100 cc. of nitric acid (1:1), made up to 500 cc. with water, and 100 cc. of the filtrate treated with sulphuric acid but without potassium sulphate, except that soils poor in calcium require the potassium sulphate.

Determining phosphoric acid by Neumann's method, J. M. KRASSER (Ztschr. Untersuch. Nahr. u. Genussmtrl., 21 (1911), No. 3, pp. 198-200).—According to the author good results can be obtained in estimating the phosphoric acid in canned soups and similar goods with the Neumann method (E. S. R., 12, p. 21; 20, p. 111) when the necessary precautions are taken. See also previous notes (E. S. R., 20, p. 610. and above).

Some methods of analyses for soil investigations, A. VESTERBERG (Verhandl. Internat. Agrocol. Konf. [Stockholm], 2 (1910), pp. 133-141, fig. 1).—A method for the titrametric estimation of carbon dioxide, carbonates, etc., in soils, which was previously noted (E. S. R., 23, p. 10) is again described, and the author points out the advantages to be derived from its use. In addition, he discusses and describes a simplified Pouget and Chouckak method (E. S. R., 20, p. 111) for the estimation of peat and humus in clay soils, and one for titrating humic acid solutions, and a rapid field method for approximately determining the calcium in the soil which depends upon the interaction of calcium carbonate and ferric chloride, the residual ferric chloride being determined with potassium sulphocyanate. The author also points out the neces-
sity of setting up a uniform procedure for determining the reaction of the soil, and calls attention to some inaccuracies in the method in which phenolphthalein is used. The value of estimating the amount of water-soluble salts in soils by the electrical conductivity method (E. S. R., 21, p. 210) is discussed and accompanied by the results of tests with Swedish soils.

A biochemical reaction for detecting pollution in water supplies, A. W. Sellards and E. Bartow (Amer. Jour. Pub. H'y., 20 (1910), No. 3, pp. 682–688).—A bacteriological-chemical method is described, with which it is possible to tell the source of the ammonia in water and also the significance of the free ammonia estimation in sanitary water analysis.

Method for the analysis of fat, David (Compt. Rend. Acad. Sci. [Paris], 151 (1910), No. 81, pp. 756, 757).—The method depends on the fact that the ammoniacal salts of the solid fatty acids are completely insoluble in an excess of ammonia. These are collected and decomposed on the filter with hydrochloric acid and weighed directly as fatty acid.

In regard to the Kumagawa-Suto method for fat, Y. Shimizu (Biochem. Ztschr., 28 (1910), No. 3–4, pp. 237–273).—The method, according to the author, gives reliable results when fresh tissues and organs are employed, but low results are obtained if large quantities of the fresh tissues are dried on the water-bath prior to extracting the fat. Aiding the drying process with alcohol did not seem to remedy this. The loss in some cases where drying was resorted to with alcohol was as high as 10 per cent, while with small quantities of material when drying was assisted with alcohol the loss was under 1 per cent. The loss of fat is attributed to the oxidation of the fatty acids, and when tissues are to be dried this should be done in a dry vacuum without heat. The method did not give good results with blood.

Determination of fat in foods, E. Polenske (Arb. K. Gsundtsamt., 33 (1910), No. 3, pp. 563–579).—After discussing the comparative value of the usual hot extraction method and the shaking out method for estimating fat in foods, the author describes a new shaking out method for determining fat in plant substances. In this method the material is first treated with hydrochloric acid in a boiling water bath, and after cooling the fat is extracted by shaking with ether and petroleum ether. The results with the method and various cereals, legumes, meat, and dairy products are given.

Determination of solids in vinegar, R. T. Mohan (Pure Products, 7 (1911), No. 1, pp. 22, 23, fig. 1).—The author points out that the official method for estimating the total solids in vinegar by evaporation is faulty, because some of the volatile acid is not driven off. In its stead he recommends using sensitive standardized hydrometers for determining the specific gravity of the vinegar, and presents a correction table for use with such instruments.

Estimation of phosphoric acid in ciders and vinegars, F. F. Hasbrouck (Pure Products, 6 (1910), No. 10, pp. 583–585).—The author describes a composite volumetric method, in which either acid or alkali or ammonia and potassium permanganate are employed as the titrating agents.

Honey fermentation and some notes in regard to the chemical composition of honey, T. Nussbaumer (Ztschr. Untersuch. Nähr. u. Genussm., 20 (1910), No. 5, pp. 272–277).—The author found several species of zygoseraccharomyces in numerous samples of honeys and from different sources, the origin of which could not be determined. Natural honeys did not generally give the Fiehe reaction. Foreign honeys gave a lesser protein precipitate (Lund) than European honeys.

Identification test for caramel, G. H. P. Lichthardt (Jour. Indus. and Engin. Chem., 2 (1910), No. 9, p. 389).—The following reagent for detecting caramel in vinegars, liquor, and flavoring extracts has given good results in the hands of the author: Tannic acid 1 gm., sulphuric acid (specific gravity 1.84) 0.75 gm., and enough water to make 50 gm.

Saffron and its adulteration, E. Collin (Ann. Falsif., 3 (1910), No. 23, pp. 353–359, figs. 14).—This article describes the usual microscopical appearance of saffron and discusses the normal and abnormal impurities in the commercial article.

Distilled liquors: Whisky (rye, Bourbon, and Scotch), brandy (cognac), and gin, W. O. Holmes (Philippine Jour. Sci., A. Chem. and Geol. Sci., 5 (1910), No. 1, pp. 23–28).—A study of methods, with some recommendations, and analyses of distilled liquors which entered the port of Manila.

The bitter acid content of Hungarian hops, G. Biró (Kisérlet Közlem., 13 (1910), No. 4, pp. 349–327).—The author examined 33 samples of Hungarian hops and found the average bitter acid content to be 3.38 per cent, the maximum 4.89 per cent, and the minimum 1.76 per cent.

The sources of error in the Folin method for the estimation of creatinin, A. E. Taylor (Jour. Biol. Chem., 9 (1911), No. 1, pp. 19, 20).—Among the sources of error in this method (E. S. R., 17, p. 165) pointed out by this author are the range of concentration (5 to 15 mg. in the volume to be tested), the varying intensity and quantity of normal and abnormal urinary pigments, dilution in its relation to the amount of picric acid employed, the eye in the absence of standardized light, and the kind of light used. “Under ideal conditions, the method will enable one to estimate 10 mg. of creatinin with an accuracy of plus or minus 0.1 mg.”

A modified guaiac test with sodium peroxid. B. Bardach and S. Silberstein (Ztschr. Physiol. Chem., 65 (1910), No. 5–6, pp. 511, 512; abs. in Zentral. Biochem. u. Biophys., 10 (1910), No. 9–10, p. 462).—The test is carried out as follows:

To 5 cc. of the fluid to be examined add a freshly prepared alcoholic solution of guaiac dropwise until the fluid begins to become opaque, and then a knife point of sodium peroxid, following quickly with 2 cc. of a 30 per cent acetic acid solution, and covering the mixture with a layer of alcohol. Even when small traces of the blood or other reacting substance are present a blue ring is obtained.

The chemical processes involved in the coagulation of milk by rennet, I. Bang (Skand. Arch. Physiol., 25 (1911), No. 1–3, pp. 105–144).—The results of these extensive experiments show that the processes involved in the coagulation of milk are exceedingly complex.

In the case of the calcium salts it could be noted that these are distributed among the organic and inorganic acids, lactalbumin, lactoglobulin, and casein.
Casein, on the other hand, reacts with certain bases as an acid. It was further noted that long before the actual coagulation takes place paracaseins are successively produced, with always a greater and greater affinity for calcium phosphate. As a result of this the paracasein takes up more and more calcium phosphate, until finally so much is in combination with it that coagulation takes place.

Coagulation, according to the author, is many phased. There are first numerous phases of paracasein formation, and in the others the combination of paracasein and the calcium phosphate takes place, this probably requiring the longest time for its execution. The author does not believe that rennet should be classed among the coagulating enzymes, as the coagulation of the paracasein is in reality brought about by the calcium salts and therefore can not be considered a true coagulation.

Contribution to our knowledge of milk catalase, F. Spindler (Biochem. Ztschr., 30 (1911), No. 5, pp. 384–412, fig. 1).—This work, which was conducted with Lobeck's apparatus (E. S. R., 23, p. 13), brought out the fact that the highest catalytic power was present in goats', cows', and pigs' colostrum and which is smaller if the sample is taken after milking or feeding the young.

An abnormal catalase figure (as compared with normal milk) is usually present for 8 days after birth, but if present after that time it is due to an inflammation of the mammary gland. Mastitis milks have a large catalytic power throughout the whole cycle of the disease, and sometimes retain it for considerable time after the disease is no longer apparent. Udder diseases, such as abscess and necrotic areas in the glands, cow pox, and udder furunculosis also yield a milk with a high catalytic figure. In other diseases, such as peritonitis and tuberculosis (without udder involvement), a large figure may be present during certain stages of the disease.

Fresh milk rich in catalase is usually alkaline, and in many instances an undiseased gland will yield more than the standard amount of oxygen (2.5 cc. from 15 cc. of milk). Milks which have an addition of sodium bicarbonate, and those obtained from practically dry and sterile animals, also have a high catalase content. The author points out the value which the test may have for identifying diseased quarters, but states that the limit of 2.5 cc. is much too low. It was found that goat's milk at times yields very low figures and at other times abnormally large figures for catalase. Yogurt and kefir yield high catalase figures, but these are proportionate to the age of the milk product.

Estimation of catalase in milk, von Hetyendorff and Meurer (Milchw., Zentbl., 6 (1910), No. 12, pp. 529–533).—The authors determined the oxidizing capacity (catalytic activity) of various milks with Lobeck's apparatus (E. S. R., 23, p. 13) and under varying conditions. In conjunction with this, the bacterial content of milk was also noted. The results show that the oxidizing capacity rises with an increase in bacterial content, and that where a high catalytic power is present a large bacterial content is to be expected.

Detection and determination of nitrates in milk by the diphenylamin-sulphuric acid reaction, J. Tillmans (Ztschr. Untersuch. Nahr. u. Genussm., 20 (1910), No. 11, pp. 676–707; Molk. Ztg. Berlin, 21 (1911), Nos. 2, pp. 16, 17; 3, pp. 26–28).—The reaction has been very thoroughly examined by the author, who finds that the presence of small amounts of chlorids seems to be essential to the development of the coloration obtained with the diphenylamin-sulphuric acid reagent with small and relatively large amounts of nitrates. The reaction is also of value for nitrates, the only difference being that with nitrites the reaction appears quicker, and that chlorids are not necessary. Proteins, particularly peptones, and milk fat prevent the formation of the blue color, but the milk can be freed from all objectionable bodies by treating it
with calcium hydrate and shaking the fat out with ether before making the test. Milk serum which contains as little as 0.25 mg. of nitric acid (N₂O₅) per liter gives a distinct blue coloration.

The test can be used quantitatively and allows the detection of as little as 5 per cent of added water to milk where the water contains not less than 10 mg. of nitric acid (N₂O₅) per liter. Milk which contains much dirt will yield a slight coloration with the reagent, but the presence of a little of such matter does not affect the test.

The qualitative test is conducted as follows: Two cc. of the reagent (0.085 gm. diphenylamin and 100 cc. dilute sulphuric acid 1:3, shaken carefully until the diphenylamin dissolves, made up to nearly 500 cc. with concentrated sulphuric acid, cooled, and filled to the mark with the same acid) is placed in a test tube with 0.5 cc. of the water or milk serum (whichever is to be tested), and the mixture shaken and cooled. A distinct maximum blue coloration is obtained in about 1 hour if nitrates are present.

**A method for the estimation of citric acid in milk.** F. Desmoulière (*Bul. Sci. Pharmacol.*, 17 (1910), No. 10, pp. 588-59).—The method is as follows:

To 200 cc. of milk add 100 cc. of a 2 per cent acetic acid solution, bring the mixture to the boiling point, cool, filter off 150 cc. of clear filtrate, and evaporate on the water bath. The addition of from 2 to 3 gm. of sea sand and frequent agitation of the mass facilitates the drying process. After drying, cool the dish and its contents, add 3 cc. of dilute sulphuric acid (0.2 gm. per cubic centimeter), and allow to stand for 3 hours, stirring from time to time. After this period add another 3 gm. of sand to the mass and extract the citric acid with ether saturated with water. Allow the ethereal layer to separate, draw it off, evaporate the ether, and take up the residue with water.

The aqueous solution thus obtained contains citric acid, acetic acid, and a little phosphoric acid. The phosphoric acid and acetic acid are then determined and subtracted from the total acidity, the remainder of which will represent the citric acid.

**A method for the estimation of reducing sugars.** S. R. Benedict (*Jour. Biol. Chem.*, 9 (1911), No. 1, pp. 57-59).—This is a modification of a method previously described (E. S. R., 19, p. 8) and another noted somewhat later,a which employs sodium citrate in addition to the other reagents.

The solution has the following composition: “Copper sulphate (crystallized) 18 gm., sodium carbonate (crystallized) 200 gm., sodium citrate 200 gm., potassium sulphocyanate 125 gm., 5 per cent potassium ferrocyanid solution 5 cc., distilled water to provide a total volume of 1,000 cc. With the aid of heat dissolve the citrate, carbonate, and sulphocyanate in enough water to make about 800 cc. of the mixture, and filter. Dissolve the copper sulphate separately in about 100 cc. of water and pour the solution slowly into the other liquid, with constant stirring. Add the ferrocyanid solution, cool, and dilute to exactly 1 liter. Of the various constituents, only the copper salt need be weighed with exactness. Twenty-five cc. of the reagent are reduced by 0.050 gm. of glucose, or by 0.053 gm. of levulose.”

The directions for conducting the tests are as follows: “Measure 25 cc. of the reagent into a porcelain evaporation dish (25 to 30 cm. in diameter) and add 10 to 20 gm. of crystallized sodium carbonate (or one-half the weight of the anhydrous salt) and a very small quantity of powdered pumice stone. Heat the mixture to vigorous boiling over a free flame and run in the sugar solution quite rapidly until a heavy white precipitate is produced and the blue color of the solution begins to diminish perceptibly. From this point the

---

sugar solution is run in more and more slowly, with constant vigorous boiling, until the disappearance of the last trace of blue color, which marks the endpoint. . . . In applying this process to urine, the latter should be diluted 1:10, unless the sugar content is known to be very slight.

**Invert sugar and its importance for seed beet polarization, W. Stephani (Bl. Zuckerrübenbau, 17 (1910), Nos. 13, pp. 213–217; 11, pp. 234–238).**—The author points out the importance of determining the sugars (by polarization) of seed feed beets and gives the procedure for this.

**Methods for examining the raw materials, products, and by-products of the sugar industry, R. Prüfling (Anleitung zur Untersuchung der für die Zuckerindustrie in Betracht kommenden Rohmaterialien, Produkte, Nebenprodukte, und Hilfsstoffen, BrunswicK, 1911, 7 ed., rev. and ed., pp. XVIII + 535, figs. 140).**—This is the seventh revised and enlarged edition of this work. Among the topics with which it deals are sugar and sugar-containing substances, bone charcoal, water, limestone, saturation gas, sodium carbonate and hydrate, hydrochloric acid, chimney and furnace gases, artificial fertilizers, sugar-beet seeds, and molasses feeds.

**The determination of nicotin in nicotin solutions and tobacco extracts, R. M. Chapin (U. S. Dept. Agr., Bur. Anim. Indus., Bul. 133, pp. 22).**—This bulletin describes an accurate and rapid method for the determination of nicotin, which is especially applicable to the examination of nicotin-containing sheep dips and scabicides.

The Kissling method adopted as official yields, according to the author, good results in experienced hands and in the absence of interfering substances, but its use by the unwary is liable to lead to considerable error. Toth's method was found to check up well with the Kissling method, but requires considerable time for the preparation of the samples, and as in the Kissling method the presence of pyridine bases in the extract may yield erroneous results.

The author has utilized the general principles involved in the Bertrand and Javillier silicotungstic acid method, in which the nicotin is precipitated from its hydrochloric acid solution with silicotungstic acid, the nicotin freed from this combination with calcined magnesia, and distilled in the usual manner and titrated. He has introduced, however, several modifications for rendering it more accurate and rapid, the chief one being the weighing of the incineration residue from the nicotin silicotungstate. This is termed the anhydrid method.

Comparative analytical results with the methods and commercial nicotine preparations are reported.

**Commercial turpentines: Their quality and methods for their examination, F. P. Veitch and M. G. Donk (U. S. Dept. Agr., Bur. Chem, Bul. 135, pp. 46, fig. 1).**—This bulletin, in addition to proposing and describing improved and simplified methods for the analyses and testing of turpentines, shows the extent to which turpentine is adulterated (most commonly with petroleum oil), indicates the losses undergone by turpentine farmers, and presents other data.

It was noted that turpentines which had not been adulterated, in the sense that nothing had been added to or removed from them, showed great variations upon analysis. This was particularly the case with old turpentines. Where adulteration was discovered in the turpentine belt it was mostly in goods in the hands of the primary buyers and dealers, the samples from the producers being only occasionally adulterated. The adulteration, however, was greatest outside the turpentine belt. Standard samples obtained from authentic sources were found to be far from uniform in regard to color.

---

The authors propose the following specifications for turpentine, which are applicable for gum spirits turpentine and wood turpentine: "Standard or No. 1 turpentine should have a specific gravity at 20° C. of from 0.862 to 0.870; a refractive index at 20° C. of from 1.468 to 1.476; 55 per cent should distill below 170° C., and a layer of not less than 200 mm. should be required to equal in color the Lovibond yellow glass No. 1. On polymerization with 38 normal sulfurous acid the residue should not exceed 1 per cent, should be reddish in color and viscous, and its refractive index at 20° C. should be from 1.500 to 1.520. An undulterated turpentine which does not agree with these requirements may properly be regarded as not of standard or No. 1 quality."

Second quality or No. 2 turpentine should have the same specific gravity and refractive index requirements, and 90 per cent should distill below 170° C. and a depth of not less than 100 mm. should be required to equal the Lovibond yellow glass No. 1. The polymerization residue must not exceed 1 per cent and must have a refractive index of not less than 1.50.

Third quality or No. 3 turpentine should have a specific gravity at 20° C. or from 0.865 to 0.880; a refractive index at 20° C. of from 1.468 to 1.485; 60 per cent should distill below 170° C. and a depth of not less than 50 mm. should be required to equal the Lovibond yellow glass No. 1. The polymerization residue must not exceed 1 per cent and must have a refractive index of not less than 1.500.

Tabulated results of the examination of many samples obtained from producers, primary buyers, and dealers are given, from inside and outside of the turpentine belt.

METEOROLOGY—WATER.

The atmosphere: Its characteristics and dynamics, F. J. B. Cordeiro (New York and London, 1910, pp. VIII+129, figs. 35).—This book treats quite exhaustively of the characteristics and circulation of the atmosphere, attempting to correct and complete work on this subject from the point where Ferrel left it.

"Since the work is necessarily purely mathematical, all methods and demonstrations have been presented in the simplest manner possible, so that they may be understood by the greatest possible number of readers.

"The general circulation of the atmosphere, which is treated at some length, has been found to be essentially different from Ferrel's earlier as well as his later conceptions of it. The mechanics of certain nonmeteorological phenomena, such as sound, and those coming under the head of light, electricity, etc., have been explained in a simple manner."

Nitrates in the air of southern regions, A. Münz and E. Lainé (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 4, pp. 166-169).—This article reports the results of examination of samples of rain and snow collected in different parts of the southern hemisphere during the Charcot expedition to the Antarctic regions.

The amounts of nitrates found in these samples did not vary materially from those found in the snow and rain of temperate regions of Europe, the average for rain being 0.225 mg. per liter and in snow 0.233 mg. per liter. There was no opportunity to study possible correlation between the nitrate content of the air and the appearance of polar auroras.

The influence of the moon on plant growth, C. Flammarion (Bull. Méc. Off. Renseign. Agr. [Paris], 9 (1910), No. 11, pp. 1264-1267).—In a previous publication (E. S. R., 17, p. 532) the author reported experiments to determine the effect of the phase of the moon at the time of planting on a number of vegetables, and these experiments have continued for a considerable period.
In 28 cases the greatest yield corresponded to planting at the time of the new moon, 29 to planting in the first quarter, 28 at the time of the full moon, and 27 in the last quarter, there apparently being no material difference to be attributed to the influence of the moon.

Monthly Weather Review (Mo. Weather Rev., 38 (1910), Nos. 11, pp. 1625-1774; figs. 3, charts 33; 12, pp. 1775-1927, figs. 3, charts 31).—In addition to the usual climatological summaries, weather forecasts and warnings for November and December, 1910, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology and seismology, a condensed climatological summary, and climatological tables and charts, these numbers contain a paper entitled The Waterpower Resources of Georgia (ills.), by C. F. von Herrmann, and the following special papers:

No. 11.—The Drought of 1910 in Kansas, by S. D. Flora; Irrigation in Salt River Valley, Arizona, by L. N. Jesunofsky; Peaches and Climate, by W. T. Clarke; and A Peculiar Squall (ills.), by A. G. McAdie.

No. 12.—Are the Springs Colder Now? by G. Reeder; New Site for the Colorado River Dam, by L. N. Jesunofsky; Weather Bureau Records and Their Use, by W. W. McLaughlin; Seasonal Precipitation Measurements, by J. C. Alter; Experiments in Frost Protection (ills.), by A. G. McAdie (see p. 37); and Fog and Frost in the San Gabriel Valley (ills.), by A. G. McAdie.

Meteorological observations (Michigan Sta. Rpt. 1910, pp. 187-200).—Tabulated daily and monthly summaries are given of observations during 1909 at East Lansing, Mich., on temperature, pressure, precipitation, cloudiness, wind movement, etc.

Note on the amount of silt carried by the Nile during the floods of 1908 and 1910, F. Hughes (Cairo Sci. Jour., 5 (1911), No. 53, pp. 29-36).—This article reports and discusses results of silt determinations in samples of flood waters of the Nile collected near Cairo and from other parts of the river and in some of the irrigation canals, the object being to ascertain the variation in the amount of suspended matter at different depths in the water and at different points in the course of its flow, and thus to show what part of the suspended matter reaches the land under the present conditions of perennial irrigation.

The results "demonstrate very clearly that the loss of suspended matter as the water traverses the canals and miskals is very largely confined to the coarser material and as a result the deposit which reaches the land under the present system of irrigation has a tendency to form a heavier soil than that which would be obtained by the basin system. In this latter, almost the whole of the suspended matter is left on the land and the small part which may escape deposition consists of the very finest of the material. Its quantity is, however, very small."

The artesian water supply of eastern Florida, E. H. Sellards and H. Gunter (Fla. Geol. Survey Ann. Rpt., 3 (1910), pp. 77-195, pls. 6, figs. 11).—This is a second paper on the water supply of Florida, the first dealing with the underground waters of central Florida (E. S. R., 19, p. 313).

It is stated that there are three principal areas in which flowing wells are found in Florida, namely, the Atlantic coast area, the Southern Gulf coast area, and the Western Gulf coast area. The Atlantic coast area is described in detail in this report. "This flowing area includes much of Nassau and Duval counties, and with the exception of local elevated areas all of St. Johns County; it follows the valley of the St. Johns River almost if not quite to the head waters, while a narrow strip reaches south along the Atlantic coast for 250 to 300 miles."

A brief account is given of the geology and soils of the region.
Sterilization of water on a large scale by means of ultraviolet rays (Lancet [London], 1910, II, No. 25, pp. 1781–1786, fig. 1).—The results of experiments with apparatus recently proposed for this purpose are summarized in this article.

SOILS—FERTILIZERS.

The gumbo soils of Iowa, W. H. Stevenson and J. F. Barker (Iowa Sta. Bul. 119, pp. 284–305, figs. 2, map 1).—The work here reported consisted of drainage, cultural, and fertilizer tests, and of physical and chemical analyses of Iowa gumbo soils. "The term 'gumbo' as used in this bulletin refers to heavy, black clay surface soil, and not to the almost impervious gray or yellow clay subsurface soil which geologists refer to as gumbo and which is locally often called hardpan."

The soils are classed with the heaviest clays, based on analyses which showed 90 to 97 per cent of silt and clay, the remainder being very fine sand. The clay content ran from 25 to 50 per cent, and is believed to be a water deposit of recent origin, the rock flour being carried down from melting glaciers.

Chemical analyses of the soil showed an average of only 0.3 per cent of nitrogen, 0.049 per cent of phosphoric acid, and 2.06 per cent of lime, but only a trifling amount of the lime was present as carbonate. The percentage of organic matter was found to be relatively low.

Tile draining was successful wherever a good outlet could be had. The soil was improved by fall plowing, and the use of clover or some green manure. The use of lime, even in large amounts, did not seem to improve the physical properties of the soil.

The management of heavy clay soils, A. R. Whitson and E. J. Delwiche (Wisconsin Sta. Bul. 202, pp. 3–17, figs. 6).—This bulletin is based upon observations and experiments made at the Superior and Ashland substations and elsewhere in the State.

"The most extensive class of clay soils which is at all heavy is that known as the heavy red clay, which occurs along the southern shores of Lake Superior, in the valley of the Fox River, and to a much less extent along the shore of Lake Michigan. The total area of this type is estimated at 3,000,000 acres. Smaller areas of moderately heavy clay soils occur in other sections of the State. When properly managed, these soils are very productive, their very fineness giving them a large water-holding capacity which adapts them especially to small grains and grasses. The largest areas of this clay are located where there are climatic conditions favorable to these crops."

The principal defect of these soils is the tendency to pack and thus become difficult to cultivate. The means suggested for overcoming this difficulty include the exercise of great care to plow only when the soil is in proper moisture condition, to drain, and to practice a 4 or 5 year rotation, including clovers, small grains, and tilled crops such as corn, potatoes, and rutabagas. It is also considered "necessary to add considerable vegetable matter by turning under an occasional second crop of clover or other legume as well as by using all available manure. Clay soils rarely contain much humus even in the natural state. The supply of phosphorus is also limited and should be increased by the addition of phosphate fertilizer supplementing farm manure."

The improvement of sandy soils, A. R. Whitson and F. J. Sievers (Wisconsin Sta. Bul. 204, pp. 25, figs. 6).—It is stated that "Wisconsin contains between four and five million acres of soil which farmers generally classify as 'sandy.' Approximately three million acres of these lands lie in the central and southern portions of the State and are already settled and in farms. The remaining area, between one and two million acres in extent, occurs chiefly in
three sections of the northern part of the State; one in the northeast, another in the north-central portion, largely in Oneida and Vilas counties, and the third in the northwestern portion.

From observations and experiments on such soils in different parts of the State the authors recommend a system of cultivation, cropping, and fertilizing which is designed to supply the deficiency of these soils in organic matter and nitrogen, phosphoric acid, and potash, correct acidity, and improve their physical condition.

The development of marsh soils, A. R. Whitson and F. J. Sievers (Wisconsin Sta. Bul. 206, pp. 22, figs. 8).—It is stated that "Wisconsin has between two and one-half and three million acres of marsh lands. While a part of this area is in large marshes of 25,000 to 100,000 acres, by far the largest area occurs in smaller tracts scattered over a large portion of the State. The only considerable part of the State largely devoid of marsh land is in the extreme southwestern section. As a result of the wide distribution of these lands, thousands of farms contain a small area of this class of soil."

Observations and experiments on soils of this character in different parts of the State led to the conclusion that with proper drainage and soil management much of this land can be made very productive. The first requirement is the organization of drainage districts to secure drainage on a large scale.

"Proper tillage of marsh lands is of the utmost importance. Heavy rolling, by packing the loose peat soil, produces a firmer seed bed which is better adapted to cultivated crops, especially small grains."

"Fertilization of marsh soils is important on account of the unbalanced condition of the elements which they contain. Marsh soils are excessively rich in nitrogen, but are frequently deficient in phosphorus and potash. While barnyard manure will supply the last two elements, these can be supplied in commercial fertilizers, allowing the use of barnyard manure on upland soils where its nitrogen as well as its mineral elements are needed. Under such special conditions it is profitable to use commercial fertilizers supplementing the manure of the farm."

"Acidity develops in marsh soils quite commonly where lime carbonate is not brought in from surrounding higher land. This acidity, however, does not interfere with the growth of crops provided the soil is properly fertilized. Very commonly acid soils require phosphate fertilizers as well as potash. The acidity of marsh soils in the southeastern part of the State is very generally neutralized by the lime carbonate in the water seeping in from the surrounding higher lands of this limestone section."

"The crops best adapted to marsh lands include corn, potatoes, cabbage, buckwheat, and timothy and alsike clover for hay. When the soil is thoroughly firmed by rolling, small grains can be grown, of which wheat and barley are best, with oats and rye second. Excellent tame grass pastures can be developed on these marshes with proper care."

Contribution to the theory of soil drainage, E. Krüger (Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 3 (1911), No. 3, pp. 157-163, pls. 3, figs. 6).—The author discusses Spöttle's theory of soil drainage, and reports results of drainage investigations from which the following conclusions are drawn:

As the distance from the drain increased the effect of drainage on the water level was in proportion to the square root of the depth, and was the same for heavy and light soils. Given the same distance between drains, the drainage of a field was more uniform for a pervious than for an impervious soil. The discharge increased with the permeability of the soil, but was substantially less rapid than the latter. However, the increase in discharge was greater with deeper than with shallower drains, thus showing the superiority of the former,
Lysimeter investigations, 1910, E. Krüger (Mitt. Kaiser Wilhelms Inst. Landw., Bromberg, 3 (1911), No. 3, pp. 163-174).—From results of investigations in which the relations between precipitation, leaching, and evaporation were studied with soils receiving normal amounts of potash, phosphoric acid, and nitrogen fertilizers, and using rye as a crop, the author concludes that the amount of water leached out of a fallow soil for the year was 55 per cent of the rainfall, as compared with 20 to 25 per cent for a cropped soil.

During the months of greatest crop growth the amount of water leached out was from 1 to 3 per cent of the rainfall for the cropped soil as compared with 60 per cent for the fallow soil. During the time of heaviest application of water (in May) only 0.02 mm. was leached out, which indicates that during the period of plant growth large quantities of water may be applied to the soil without danger of leaching. The amount of water evaporated was much greater in the cropped than in the fallow soil, being 3.7 mm. and 0.9 mm. per day respectively. The amount of water evaporated for the year was 76 per cent of the precipitation.

The amount of water transpired by the plants was small during winter but considerable during the growing period. From October to June an average of 488 lbs. of water was required for the production of 1 lb. dry matter, as compared with 348 lbs. of water from April to June. The amount of water transpired by the plant from October to June per pound of plant substance produced was 234 lbs. as compared with 219 lbs. from April to June.

The water requirements of the plants increased rapidly with their growth. The amount of water evaporated from the soil after harvesting was greatly reduced by cultivation, and such reduction of evaporation from the soil increased leaching.

Investigation on the adequacy of nutrients in forest soil, H. Vater (Tharand, Forstl. Jahrb., 59 (1909), No. 2, pp. 213-260; Naturw. Ztschr. Forst u. Landw., 8 (1910), No. 12, pp. 570-577).—The law of minimum, especially as applied to plant food in forest soils, is discussed, and experiments during 2 years with fertilizers on a forest soil on which spruce and pine seedlings were grown are reported.

As a rule nitrogen was the element present in minimum amount in the soils experimented with, and next to nitrogen phosphoric acid was the most deficient constituent. The growth of spruce and pine seedlings on unfertilized soil varied between 7 and 48 per cent of that on fully fertilized soil. The results from liming were irregular and inconclusive. The application of fertilizers reduced the amount of water required to produce a unit weight of growth.

The absorptive capacity of soils from the physico-chemical standpoint, U. Pratolongo (R. Ist. Lombardo Sci. e Let. Rend., 2. ser., 43 (1910), No. 16, pp. 542-555; abs. in Chem. Zentralbl., 1910, II, No. 24, p. 1773).—The author concludes from his investigations that the compounds which determine the absorptive capacity of soils may be divided according to the phase rule only into solid solutions and absorptive compounds. A study of their behavior toward solvents indicates that they are entirely or almost exclusively absorptive compounds.

Tests of an osmotic theory of plant distribution, G. Gola (Ann. Bot. [Rome], 8 (1910), No. 3, pp. 275-548, pls. 2).—This article sets forth at length the author's investigations on the relation between the natural distribution of plants and the composition and concentration of soil solutions in its bearing upon osmotic pressure. He proposes an elaborate classification of soils and plants on this basis.
Clod analysis, a means of determining soil structure, H. Puchner (Mitt. Deut. Landw. Gesell., 26 (1911), No. 4, pp. 38-40).—The author describes a method of clod analysis which he has used with satisfactory results in determining the structure of cultivated soils and in studying the thoroughness of cultivation with different forms of tillage implements.

By means of sieves the soil samples are separated into crumbs (Krümel) less than 20 mm. in diameter, fine clods (Brocken) 20 to 40 mm. in diameter, and clods (Klumpen) over 40 mm. in diameter. Examinations of a number of samples of cultivated and uncultivated soils taken at different depths from the surface down to 400 mm. are reported.

The formation and properties of humus substances, P. Ehrenberg (Chem. Ztg., 34 (1910), No. 130, pp. 1157, 1158; abs. in Chem. Zentralbl., 1910, II, No. 24, p. 1773; Chem. Abs., 5 (1911), No. 6, pp. 1147, 1148).—This article briefly summarizes the work of the author and other investigators on different kinds of humus and humus-like substances derived from different sources by various natural and artificial processes.

The author calls attention to the fact that while comparatively little is known of the actual composition of such substances, apparently two classes of compounds are produced in the process of humus formation, (1) those derived from carbohydrates and having an acid reaction, and (2) those derived from benzo derivatives and having an alkaline reaction. The importance of further investigations on the composition and properties of humus is emphasized.

The question of the study of humus substances, C. Blacher (Chem. Ztg., 34 (1910), No. 148, pp. 1314, 1315).—Observations on the behavior of humus compounds in boiler water are recorded.

On the escape of ammonia from manure during and after hauling to the field, P. Liechti and E. Ritter (Landw. Jahrb. Schweiz, 24 (1910), No. 7, pp. 481-525, pl. 1, figs. 3).—The authors report investigations from which they conclude that the loss of ammonia during the hauling of manure is so small that it may be entirely disregarded, but that the loss under the usual methods of applying manure to the soil is considerable. A special piece of apparatus was designed and used to determine the ammonia given off into the air under different methods of application of manure.

The losses of ammonia were found to be especially large when the manure was applied on snow, amounting in the course of a few days to one-third or more of that in the manure, and this is considered less than would actually occur under ordinary methods of manuring. The loss was determined to a large extent by the temperature. With temperatures above 0° C. the loss on snow-covered soil was very small. At temperatures below 0° the losses were greater.

The importance of peat for the manufacture of nitrogenous fertilizers, R. Schorr (Jour. Amer. Peat Soc., 3 (1911), No. 3-4, pp. 226-232).—Data are presented to show that the present sources of nitrogenous fertilizers are inadequate, and the advisability of investigating the possibility of using peat for this purpose is suggested. The efficiency of various processes which have been proposed for the manufacture of nitrogenous compounds from peat is briefly discussed.

Problems in peat filler production, J. N. Hoff (Jour. Amer. Peat Soc., 3 (1911), No. 3-4, pp. 192-201).—It is stated that there are at the present time four or five plants producing peat filler in the United States in commercial quantities, the total output being perhaps from 15,000 to 20,000 tons per year. The methods used are described. The author is of the opinion that peat makes an ideal filler, although objection has been raised to it on account of the low availability of the nitrogen as compared with that of blood, tankage, or ammonium salts,
The world movement of nitrogen in 1910, A. Bertrand (Engrais, 26 (1911), No. 7, pp. 180-191, dgm. 10).—Statistics of production and consumption of nitrate of soda and ammonium sulphate are graphically presented.

Nitrate of soda (Chem. Trade Jour., 43 (1911), No. 1236, pp. 74-77).—It is stated that according to the figures given out by the Nitrate Syndicate the production in 1910 was 2,436,182 tons, an increase of 350,253 tons over 1909. As a result of lower prices there was a large increase in consumption, especially in France, Germany, Belgium, Holland, and the United States. It is estimated that the average price in Europe during 1910 was about $5 less per ton than in the previous year.

Nitrate of soda in a Texas county, W. B. Phillips (Manuf. Rec., 58 (1910), No. 5, p. 53).—A brief account is given of the discovery of a deposit of nitrate of soda in Presidio County, about 45 miles south of Valentine, Texas, and analyses of samples of material containing from 5 to 71 per cent of nitrate of soda are reported. The alleged deposits have been very incompletely examined.

Ammonia production in 1910, W. N. McLravy (Engin. and Min. Jour., 91 (1911), No. 1, p. 87).—The estimated production of ammonia, reckoned as sulphate of ammonia, in the United States in 1910 is 116,000 tons as compared with 106,500 tons in 1909. The increase was derived largely from coke ovens. The consumption of sulphate of ammonia in the United States in 1910 is estimated to have been 178,000 tons, representing an increase of 55 per cent in imports of this material. The prices of the sulphate increased during the year and the outlook for the future is thought to be good.

Sulphate of ammonia (Amer. Fert., 31 (1911), No. 3, pp. 15-19).—This is an abstract of an annual review of the sulphate of ammonia market during 1910, giving statistics of production and consumption throughout the world, but especially for the United Kingdom. The total world's output is given as 1,100,000 tons, or a little less than half that of nitrate of soda; of the United Kingdom 369,000 tons; of Germany 375,000 tons; and of the United States 116,000 tons.

Recent progress in the fixation of atmospheric nitrogen, J. B. C. Ker- shaw (Chem. Trade Jour., 48 (1911), No. 1236, pp. 87-90, figs. 6).—This article records the fact that there has been marked progress recently in the commercial application of processes for the fixation of atmospheric nitrogen, and states that 100,000 horsepower is now used for this purpose with a prospect that the amount will be doubled during 1911.

Works at Niagara Falls, Canada; Notodden, Christiansand, and Rjukan, Norway; Patsch, near Innsbruck, Austria; La Roche de Rame, Savoy; and Freiburg, Saxony, are briefly described. Contemplated works at a number of other places are referred to.

The processes used are of two classes, those fixing the nitrogen in the form of calcium cyanamid and those producing nitric acid by the direct oxidation of the nitrogen of the air in the electric flame. The principal process belonging to the first class is that of Frank and Caro; the principal process of the second class is that of Birkeland and Eyde. A number of new processes for the oxidation of the nitrogen of the air have, however, been recently proposed, including the Pauling and Schönherr processes, and numerous patents on other processes have been applied for. Much investigation has recently been devoted to the subject of increasing the efficiency of the methods with promise of decided progress in this direction. For example, Haber and König have patented a process of reducing pressure and cooling the arc flame by which gases containing from 9.5 to 10 per cent of nitric acid can be produced when

95157°—No. 1—11—3
using air and 13.5 to 14 per cent when using a 50 per cent mixture of oxygen and nitrogen gas.

The fixation of the nitrogen of the air. Bachmann (Naturw. Wechschr., 26 (1911), No. 5, pp. 65-69).—Various processes which have been devised for this purpose are described and the importance of the fixation of nitrogen in relation to increasing means of supporting life is discussed.

The knowledge of lime nitrogen, N. Caro (Ztschr. Angew. Chem., 23 (1910), No. 51, pp. 2405-2417; abs. in Chem. Ztg., 35 (1911), No. 8, Rept., p. 32).—The results of investigations on the following subjects are summarized: The silver salts of cyanamid and dicyandiamid, the qualitative separation and determination of cyanamid and dicyandiamid, the determination of urea in lime nitrogen, the determination of cyanid in the presence of cyanamid and dicyandiamid, the action of cyanid on carbide, the action of carbon dioxide in lime nitrogen, the action of nitrogen on carbide and alumina, the preparation of pure cyanamid from its salts, and the action of nitrogen on a mixture of barites and lime and the influence of added substances on the carbide-forming mixture.

Potash salts: Their uses and occurrence in the United States, W. C. Phalen (U. S. Geol. Survey, Advance Chapter from Mineral Resources of the United States, Calendar Year 1910, pp. 24).—This article discusses the German potash deposits, the uses made of potash salts, the value of the imports into the United States, and the possible sources of potash in the United States.

It is stated that the United States imported $11,000,000 worth of potash salts during 1910. A large proportion of these salts is used in the manufacture of fertilizers. The possible sources of potash in the United States referred to are igneous rocks, green sand marls, waters of salt lakes in various parts of the West, alkali deposits, salt deposits in Michigan and elsewhere, wood ashes, seaweed, wool scourings, and beet-sugar molasses and residues.

The potash industry and the American farmer, A. R. Reeve (Amer. Rev. of Reviews, 43 (1911), No. 253, pp. 212-214, fig. 1).—This article describes briefly the potash deposits of Germany and discusses the conditions leading up to and involved in the controversy between the German producers and American purchasers of potash.

Potash for over 600,000 years (Amer. Fert., 34 (1911), No. 3, pp. 20-21).—This is a translation of an article by Ochsenius, published some time ago, in which it is estimated that the potash deposits of Germany are sufficient to supply the needs of the world for over 600,000 years.

Other potash deposits (Amer. Fert., 34 (1911), No. 3, pp. 34-36).—This is a translation of an article by H. Erdmann (E. S. R., 22, p. 718) describing the location, extent, and probable commercial value of the known deposits of potash salts outside of Germany.

Phonolite as a fertilizer, M. Popf (Mitt. Dcnt. Landw. Gesell., 26 (1911), No. 5, pp. 52-57).—Experiments begun in 1909 (E. S. R., 22, p. 325) were continued in 1910 to study the after-effects of phonolite as compared with potash salts.

The results confirm the conclusions from the earlier experiments and show that phonolite is in no way comparable with potash salts as a fertilizer. The results the second year were no better than in the year previous. The potash in the phonolite was for the two years about 50 per cent as effective as that of potash salts.

Feldspar as a source of potash, F. J. Machalske (Amer. Fert., 34 (1911), No. 5, pp. 17-26).—The principal potash feldspars and the various processes for rendering the potash available which have been patented are described.

Florida phosphate industry in 1910, C. G. Memminger (Engin. and Min. Jour., 91 (1911), No. 5, p. 264).—It is stated that little of commercial or techni-
cal interest with reference to the Florida phosphate industry occurred during this year. There was a marked decrease in production of hard rock phosphate and an estimated increase of 18 per cent in production of land pebble. As a result of low prices no new plants were erected. The low prices are said to have been due not to lack of demand but “to the present unfortunate method of selling whereby there is unnecessary and undue competition. As before pointed out, the only beneficiary under existing conditions is the manufacturer of superphosphate, who is thereby enabled to purchase his crude phosphate at a minimum figure, and on account of the active demand for fertilizers is enabled to sell his manufactured product at high figures. The producer and the consumer suffer; the intermediary or manufacturer profits.”

[Fertilizer markets, 1910] (Oil, Paint and Drug Reporter, 79 (1911), No. 9, pp. 55–57).—Reviews are given of the fertilizer market in New York, Baltimore, Charleston, and Philadelphia.

A large increase, variously estimated at from 15 to 25 per cent, in the fertilizer business of the United States during 1910 is reported. The increase was especially large in the South. There was a marked increase in the consumption of sulphate of ammonia, which was met by increased importations, especially from Great Britain, and by an increase of domestic production as a by-product from coke ovens. There were large increases in the production and consumption of nitrate of soda accompanied by a marked fall in prices. The practical failure of the menhaden fisheries during 1910 resulted in very high prices for fish ammoniates. The production of Florida hard rock phosphate declined and of pebble phosphate increased during the year. There was a large rate of increase in imports of potash salts growing partly out of the unsettled conditions resulting from the potash controversy.

Commercial fertilizers, B. H. Hite and F. B. Kunst (West Virginia Sta. Bul. 132, pp. 5–52).—This bulletin reports the results of analyses of commercial fertilizers inspected during the year 1910. It is stated that with few exceptions, manufacturers of commercial fertilizers doing business in West Virginia “are making every reasonable endeavor to provide the quantity of every constituent guaranteed.”

AGRICULTURAL BOTANY.

Action of anodic and cathodic liquids on germination, H. Micheels (Acad. Roy. Belg., Bul. Cl. Sci., 1910, No. 5, pp. 391–403; abs. in Jour. Chem. Soc. (London), 98 (1910), No. 576, II, p. 883).—In a previous publication (E. S. R., 23, p. 627) the author showed that the influence on germination of wheat in nutrient solutions through which a galvanic current had been passed was due to changes in the solutions. In the present paper he gives the results of further investigations on the changes induced by the electric current.

Centinormal solutions were used, and it was found that the germination was accelerated by the cathodic liquor of sodium nitrate or chlorid more than was the case with the anodic solutions. A mixture of the two gave intermediate results, and an unelectrolyzed solution was better than any of the others. Similar results were obtained for potassium nitrate and chlorid, except that
the cathodic liquor of potassium nitrate favored leaf growth more than the unelectrolyzed solution. For mixtures of potassium and sodium chloride the unelectrolyzed solution gave the best results.

In experiments carried on with Mucor the anodic solutions gave the best development, indicating that the protoplasm of the fungus differs somewhat from that of higher plants.

Filtering the solutions had practically no effect on their activity.

Concerning the action of an alternating current on germination, H. Micheels and P. De Heen (Acad. Roy. Belg., Bul. Cl. Sci., 1910, No. 8, pp. 665–668).—In continuation of the above investigations, the authors compared the effect of galvanic currents of high and low frequency, previous results having showed a favorable action for an alternating current of high frequency.

In the present paper it is shown that a continued galvanic current had a detrimental effect on germination. A weak alternating current from 6 Daniell cells did not favor the growth of roots or weight of seedlings, but it did cause an increase in the length of the leaves. Where the current was increased the results were comparable with those obtained by cathodic solutions, as explained above.

The effect of salts on the respiration of plants, A. Reinhard (Ber. Deut. Bot. Gesell., 28 (1910), No. 9, pp. 451–455).—In continuation of some previous experiments (E. S. R., 24, p. 328), the author has repeated his experiments with peas, testing the effect of a number of salts in solutions upon the respiration of the ground pea seed. Peas of the variety Victoria were ground and mixed with distilled water and salt solutions until a thick paste was formed, after which the respiration was investigated.

Neither potassium nitrate, potassium phosphate, magnesium sulphate, calcium nitrate, nor iron chloride in dilute concentrations had any effect on the respiration of the ground seed, even when the experiment was prolonged for a considerable time. Potassium nitrate and calcium nitrate showed no stimulating effect but rather had an injurious influence on the respiratory enzyms.

Origin of osmotic effects.—III. The function of hormones in stimulating enzymic change in living structures, H. E. and E. F. Armstrong (Proc. Roy. Soc. [London], Scr. B, 82 (1910), No. 559, pp. 585–602; abs. in Jour. Chem. Soc. [London], 98 (1910), No. 576, II, pp. 883, 884).—It has been shown that when a leaf of cherry laurel is exposed to the vapor of an anesthetic, hydrogen cyanid is liberated, and that not only the common anesthetics but many organic vapors have a similar effect. Weak solutions of mineral acids, alkalis, and salts are inactive, but the simpler organic acids all pass into the leaf from solutions. The behavior of the laurel leaf resembles very closely that of the barley grain (E. S. R., 21, p. 126).

It is proposed to divide substances other than colloids into 2 classes, according as they will or will not pass through the differential septa, such as occur in the barley grain and the laurel leaf. For those that will pass through the septa the term "hormone" has been suggested.

Experiments show that water passes into the leaf together with the hormone, and the hypothesis is advanced that, when introduced into the living cell, substances which are not attractive to water exercise stimulative effects that are primarily mechanical. The molecules of the hormone are interposed between the molecules in the cell by the change in the osmotic state, and an influx of water from other regions takes place. It is thought that probably the mere dilution thus effected is determinative of any changes produced. Degenerative changes which are set up tend to increase in intensity as the products of change exercise a stimulative influence, and gradually enzyms are set free which can attack the various hydrolytes stored in the cell.
The phenomena of change in living structures are said to apply to organisms in general, and this hypothesis, it is believed, will afford an explanation of a number of more recent observations on plant metabolism.

Investigations regarding the phloem and food conduction in plants, F. U. G. Agrellus (Kans. Univ. Sci. Bull., 5 (1910), No. 10, pp. 169-179, pls. 2).—A special study has been made of the devices for the transfer of food materials in the phloem of vascular plants, comparisons being made of the phloem in stems, petioles, and fruit stalks, of 72 species of plants, representing 65 genera and 39 families.

The special devices for the lateral transfer of food present in the phloem and cortex of plants are said to be the pitted cells, the arrangement of the phloem in narrow wedges, and the radially elongated medullary-ray cells which are especially adapted to conduct the food. The second device was found to be the sieve tubes, and they were demonstrated in all but three of the plants examined.

Phototaxis, assimilation, and growth, P. A. Dangerd (Bull. Soc. Bot. France, 57 (1910), No. 5, pp. 315-319).—A résumé is given of observations on the influence of light on various organisms, in which certain greenish colored bacteria were found to arrange themselves in definite parts of the spectrum.

A brief account is also presented of a method of determining the assimilation of various species of algae through the liberation of oxygen, and the effect of various colored screens corresponding to definite portions of the spectrum on the growth of algae is described.

Metabolism and translocation in young conifers, H. Bauer (Naturw. Ztschr. Forst u. Landw., 8 (1910), No. 10, pp. 457-438).—The results are given of a chemical investigation into the metabolism and translocation taking place in coniferous seedlings. Larch, hemlock, fir, and pine seedlings were used in the experiments, and the variation of their nitrogen and principal inorganic constituents was determined, analyses being made at 4 different periods, which corresponded to the times when growth was just beginning, when the new organs were beginning to appear, at the full height of growth, and at its autumnal cessation. The results are given in tabular form.

The morphology of leaf fall, E. Lee (Ann. Bot. [London], 25 (1911), No. 171, pp. 51-106, pls. 3, figs. 20).—The results are given of an anatomical study of various species of dicotyledonous plants, in which an attempt was made to determine the morphology of leaf fall.

It was found that in dicotyledonous plants the essential modification at the leaf base in connection with leaf fall is the formation of a separation layer which is produced from existing cells with or without division. The leaf separates from the stem by the disappearance of the middle lamella of the cells of the separation layer and the subsequent rupture of the sieve tubes and vessels of the leaf trace. A lignified layer may or may not be present, but a protective layer is invariably produced either before or after leaf fall. This protective layer is formed by ligno-suberization of the cells of the leaf base, or of cells produced by the continued division of a regular cambium. The protection of the tissues of the stem underlying the leaf scar is aided at a later date by the production of a layer of cork cells.

In many species the persistent leaf or leaf scar is thrown off during the second year.

Recent investigations on the glucosid of pear leaves and its rôle in autumn coloration, E. Bourquelot and Mlle. A. Richtenhofz (Jour. Pharm. et Chim., 7, ser., 3 (1911), No. 1, pp. 5-13; Compt. Rend. Soc. Biol. [Paris], 69 (1910), No. 38, pp. 605-607).—Subsequent to their discovery of a glucosid, arbutin, in pear leaves (E. S. R., 24, p. 31), the authors have examined leaves of a considerable number of species that have been referred to the genus Pyrus.
and they have been unable to find arbutin in any except the species producing the fruit known as the pear. On this account they think the test could be used in differentiating the species into separate genera. The proportion of arbutin was found to vary in pear leaves according to the stage of growth; however, it was still to be found at the end of the growing season.

A study was made of the relation of arbutin to autumn coloring of pear leaves, and some varieties were found to blacken, as claimed by Weevers (E. S. R., 24, p. 138), due to the oxidation of the arbutin. In some varieties, however, the leaves turn yellow instead of black, and this is attributed to the presence of methylarbutin in conjunction with the common glucosid. The methylarbutin hydrolyzes more rapidly than arbutin and results in a yellow coloration.

The behavior of tannin in persimmons, with some notes on ripening, F. E. Lloyd (Plant World, 14 (1911), No. 1, pp. 1-14, pl. 1).—A study has been made of the tannin in persimmons with special reference to changes taking effect on ripening.

The author found that the tannin in the tannin cells of the unripe fruit does not exist wholly in a watery solution, but is rather associated in part with a carrier somewhat analogous to a gelatin, albumin, or other colloid-tannin compound. The insolubility of the tannin in the ripe fruit is due to its intimate and complete association with the carrier, with which it unites. The behavior of the tannin is considered analogous to that of other substances which are rendered insoluble by combination.

The final stages of ripening of this and similar fruits are believed to be independent of living protoplasm, and this conclusion is confirmed by experiments in which chemical agents have been used to induce ripening earlier or more rapidly than normal.

In the normal tissue there is no intercellular tannin. When such occurs it is probably due to the bursting of the tannin cells through bruising or other injury. The capacity for imbibition on the part of the tannin masses sufficient to burst the cell wall is not associated with astringency to the taste during the whole of the period of ripening when such bursting is possible.

In the course of the investigations the author obtained evidence showing that the cell walls of the pulp are digested and that they are not composed of true cellulose, but pectocellulose.

It is probable that the above conclusions are applicable to the ripening of the date.

Plant acclimatization in southern Arizona, J. J. Thorner (Plant World, 14 (1911), No. 1, pp. 15-23).—The author gives an account of observations on attempts to acclimatize plants in southern Arizona, in which perennial plants from temperate zones were subjected to high summer temperatures and those from subtropical and tropical regions to possible frost. These two factors seem to be the limiting ones in determining the possibility of introducing a considerable number of economic and other plants. Notes are also given on the influence of soil, soil water, elevation, etc., on the introduction of plants.

The weeds of arable land in relation to the soils on which they grow, Miss W. E. Brenchley (Ann. Bot. [London], 25 (1911), No. 97, pp. 155-165).—An attempt has been made to ascertain how far weeds of arable lands are characteristically connected with particular soils and crops.
There was found to be a definite association between the species of weeds of arable lands and the soil on which they grew. The determining factor is the texture of the soil and not the geological formation from which it is derived, except with soils overlying chalk. The crop has very little influence on weeds except in the case of seed crops, which probably smother out a large number of species which would normally occur. Certain weeds were found to be definitely symptomatic of particular types of soil, though the majority of weeds are not strictly circumscribed in this respect.

**Physiological aspects of fertilization and hybridization in ferns, W. D. Hoyt** (Bot. Gaz., 49 (1910), No. 5, pp. 340–370, figs. 12).—An account is given of an investigation into the hybridization and fertilization of ferns. The results of the author's experiments were negative, but they are considered as indicating the nonoccurrence of hybrids among ferns.

The author studied the entrance of sperms into the archegonia, and the entrance was obtained in every combination of species tried. When the egg and sperms were of the same species 37 fusions resulted, but when of different species they failed to give a single fusion. The author believes from this evidence that hybrids are not formed among this class of plants.

**Do ferns hybridize? R. C. Benedict** (Science, n. ser., 33 (1911), No. 842, pp. 254, 255).—In reviewing the above paper, the author criticizes the methods and states that while it is quite true that experimental proof of the kind attempted by Hoyt is lacking, yet no one has ever observed the development of a suspected hybrid from before the period of fusion of the gametes. He claims that Hoyt's arguments against fern hybridity apply with practically equal force to most cases of accepted hybridity among flowering plants and animals.

It is said that there are a considerable number of reputed fern hybrids which possess all the characters generally recognized as characteristic of hybrids, and that the only reasonable explanation of their existence is to identify them as having been the custom.

**The rules of Naudin and Mendel's law relative to the segregation of hybrids, L. Blaringhem** (Compt. Rend. Acad. Sci. (Paris), 152 (1911), No. 2, pp. 100–102).—Attention is called to a memoir presented by Naudin to the Academy of Sciences, Paris, in 1861, giving the results of 8 years' experiments on the hybridization of Papaver, Mirabilis, Primula, Latura, Nicotiana, Petunia, Digitalis, and Linaria, from which some generalizations were deduced. These rules of Naudin are said by the author to be general principles, and the laws of Mendel are considered by him as special applications.

The two principles laid down by Naudin are as follows: (1) First generation hybrids of the same cross or reciprocal crosses will resemble each other as much or nearly as much as different individuals of any recognized species; (2) fertile hybrids and those fertilized among themselves will revert sooner or later to the specific types from which they are derived.

The author gives an account of the behavior of some crossbred barleys, the segregation of which conforms to the above rules rather than to those of Mendel.

**The mutation theory, II, H. de Vries**, trans. by J. B. Farmer and A. D. Darbishire (Chicago and London, 1910, vol. 2, pp. VIII + 633, pls. 6, figs. 149).—This volume completes the translation of the author's work on Die Mutations Theorie, the previous one having been noted elsewhere (E. S. R., 22, p. 625). In it some of the data relating to the origin of horticultural varieties are collated. This is followed by discussions of the origin of a number of eversporting varieties and their relation to the author's theory, with concluding chapters on the relation of the mutation theory to other branches of inquiry.
EXPERIMENT STATION RECORD.

On the inheritance of the yellow tinge in sweet pea coloring, Mrs. M. G. THIDAY (F. Sykes) and D. THIDAY (Proc. Cambridge Phil. Soc., 16 (1910), No. 1, pp. 71-84).—A description is given of experiments begun in 1906 on the nature and inheritance of the yellow tinge in scarlet, salmon, and deep cream-colored sweet-pea flowers. Several crosses were made and the offspring grown as far as the F₂ generation. Those resulting from a cross of Queen Alexandra and Dorothy Eckford were carried on to the F₃ and F₄ generations, and the authors describe the segregation according to color characteristics.

The deep yellow tinge in Queen Alexandra, deep salmon, and deep cream sweet-pea flowers was found to depend on 3 coincident recessive characters. Microscopical examination showed that one of the factors imparting a tinge to the whole flower, producing self-colored forms, affects the sap only, tinging it deeply. The second similarly imparts to the sap a tinge which is fainter and is commonly associated with a few yellow plastids. The third factor, which chiefly affects the standard, is connected with the occurrence of large clusters of golden-yellow plastids in the cells.

A spineless mutation of Cynara cardunculus, L. TRABUT (Bull. Soc. Bot. France, 57 (1910), No. 5, pp. 350-354, pls. 2).—The author reports the occurrence in Algeria of a spineless form of the wild cardoon which differs only in the unarmed character of the plant. It is believed that the spineless form will prove a valuable acquisition.

International catalogue of scientific literature. M—Botany (Internat. Cat. Sci. Lit., 8 (1910), pp. VIII+949).—This is the eighth edition of the International Catalogue (E. S. R., 23, p. 431), about 7,500 articles being indexed. The literature is mostly that of 1908, although there are some titles included earlier than that and a few entries of 1909.

FIELD CROPS.

A report of seven years’ investigation of dry farming methods, L. A. MERRILL (Utah Stu. Bul. 112, pp. 95-162, figs. 15).—A progress report of the first season’s investigations has been previously noted (E. S. R., 16, p. 862).

The results of variety tests made are briefly summarized in the following table:

<table>
<thead>

From the tests made at the experimental farms the author feels justified in concluding that the "growing of macaroni wheats is inadvisable on our dry..."
farms, at least for the present." Fairly good results were secured with the hemp crop. In alfalfa work it was impossible to distinguish in vegetative habit or yield among Turkestan, Sand Lucern, and Common Utah alfalfa. From 4 to 24 lbs. of seed were used, but on all the farms the lowest rate of seeding gave the best results. Planting in May or early June proved the most satisfactory. For seed production planting in rows or even in hills and intertilling proved most desirable. On the Juab county farm plats plowed in the fall of 1905 and in May, 1906, and seeded in September, 1906, yielded 35.4 and 33 bu. of wheat per acre respectively. Two plats devoted to a comparative test of spring and fall plowing at Nephi were practically equal in water content throughout the season.

"Extensive experiments . . . have not tended to confirm the importance of excessively deep plowing. . . . On the Juab farm where the soil is a heavy clay, there has not been a year when the 8 in. and 10 in. depths have not given better yields than the deep plowings. On the other farms the yields are slightly better for the deeper plowings, but certainly not enough better to warrant the extra expense incurred."

A rate of seeding test confirmed "the practice in vogue in this State, that of seeding 3 lbs. per acre."

In Juab County wheat gave average yields during the period 1904 to 1908 of 26.9 and 15.3 bu. per acre respectively, when planted 1 1/2 in. and from 2 1/2 in. to 3 in. deep. The author concludes from these experiments and from practical experience "that on heavy clay soils seeding to a depth of from 1 to 1 1/2 in. gives best results and that even in a sandy loam it is, as a rule, not safe to go beyond 3 in."

Other tests indicate that drilling one way gives better results than cross drilling or sowing broadcast. Practically no difference appeared in the height of plant, length of head, or yield of grain as a result of cross drilling. "The apparent superiority of the cross-drilled grain was due to the greater number of leaves on the plants."

A table indicates that the upper 6 ft. of soil on a fallowed plat properly cultivated contained 45 per cent more moisture than did soil that had been cropped for 7 years. Plats "cropped each year gave 73.7 bu. as compared with 53.4 bu. for the crop fallowed every other season." At the Juab county farm the average yield of Turkey Red wheat was 20.6 bu. per acre as compared with an average of 15.3 bu. for 4 common varieties. On land plowed in the ordinary way it yielded 18.6 bu. per acre as compared with markedly lower yields after plowing 5 in. and 10 in. deep and subsolling 15 in. and 18 in. deep on 4 other plats. Sowing September 1 resulted in higher yields than sowing at any earlier or later date. Two winter barleys gave an average yield of 13.1 bu. per acre as compared with 1.2 bu. obtained from spring barleys in 1910.

The methods pursued and the results obtained in these cultural tests are stated in full and discussed.

Dry farming: A system of agriculture for countries under a low rainfall, J. A. WÝDTsoE (New York, 1911, pp. XXII+445, pl. 1, figs. 111).—Successive chapters discuss dry farming as related to theoretical culture, rainfall areas, meteorology, soils, root systems of plants, the storage of water in the soil, the regulation of evaporation and transpiration, cultural methods, the selection and composition of crops, the maintenance of soil fertility, farm machinery, and irrigation. The history of dry farming in the United States is outlined, and its present status in different countries of the world is discussed. A bibliography of 84 titles is given.

References on plant breeding, C. Fruwirth (Jour. Landw., 58 (1910), No. 3, pp. 251-271).—Abstracts of a number of recent publications are presented.
The importance of the origin and improvement of grasses and clovers, H. Witte (Tidsskr. Landmæn, 1910, pp. 13; obs. in Bot. Centbl., 11) (1910), No. 32, p. 416).—Tables and descriptive text show the yielding power and other characters of varieties of clover and grass tested by seed improvement unions. The yields of varieties from foreign countries are graphically indicated, practical conclusions are drawn from experimental data, and the improvement of native forms is discussed.

Points on the indigenous and acclimated forage crops of Argentina, I, C. D. Girola (Apuntes sobre algunas Forrajes Indígenas y Aclimatados de la República Argentina. Buenos Aires, 1910, pp. 132, pls. 10).—The author devotes a separate chapter to each of the following: Brome grass (Bromus unioloides) crabgrass (Digitaria sanguinalis), yellow foxtail (Sectaria glauca), meadow grass (Poa annua), rye grass (Lolium brasilianum), Paspalum notatum, spear grass (Stipa sp.), alfalfa (Medicago sativa), white clover (Trifolium repens), bur clover (Medicago denticulata), sweet clover (Melilotus sp.), and blueweed (Echium plantagineum). A botanical description of each is followed by a statement of its cultural and climatic requirements, the results of chemical analyses, and directions for its production.

[Experiments with field crops, Barbados, 1909—10], J. R. Bovell (Imp. Dept. Agr. West Indies, Rpt. Local Dept. Agr. Barbados, 1909—10, pp. 21).—Each of the lines of work noted in preceding report (E. S. R., 23, p. 334), was continued in 1909—10. Tables report the strength and values of Sea Island, Silket, and other cottons; the yields, flavor, and other qualities of the sweet potatoes tested; the yields of economic colocasias, and meteorological data collected during 1909. During the year 25 legumes, most of which were edible, were grown to obtain seed for more extensive tests.

[Experiments with cotton and sugar cane], L. G. Corrie and J. Mitchell (Ann. Rpt. Queensland Acclin. Soc., 36 (1899). pp. 19—26, 26, 27).—Discussions of the distribution of varieties of sugar cane and of fresh importations accompany a report of the work. Average yields for 3 and 4 years on black soil were 10,120 lbs., 9,503 lbs., and 9,224 lbs. of saccharose per acre, respectively, for B.3, 204, B3, 747, and B3, 222 as compared with 6,070 lbs. per acre produced by the standard variety White Transparent. A cotton gin was set up, but the little cotton that matured was of indifferent quality.

[Manurial experiments with potatoes and turnips], A. Macpherson (Jour. New Zeal. Dept. Agr., 1 (1910), No. 5, pp. 375—379).—On an exceptionally rich soil the lowest gain in yield of potatoes over the unmanured plot followed an application of 2 cwt. of superphosphate, 1½ cwt. of bone dust, and 1½ cwt. of dried blood, while the highest gain, nearly 1 ton per acre, followed an application of the same mixture with the addition of 1 cwt. of potassium sulphate.

A table states the results of applications of 7 different fertilizer mixtures to turnip plots on each of 8 different farms.

A successful alfalfa and truck crop in southeastern Ohio, W. A. Lloyd (Ohio, Sta. Cir., 107, pp. 3—19, figs. 10).—The author outlines the operations by a means of which net returns of $3,375 were obtained during 1909. The crops grown were alfalfa, corn, wheat, potatoes, melons, and vegetables. The farm is located 5 miles from an industrial community of “probably 16,000 to 18,000 people.” Its soil and drainage and the owner’s methods of management are stated.

Investigations of the phosphoric acid and potash requirements of meadows, P. Liechti (Landw. Jahrb. Schweiz, 24 (1910), No. 4, pp. 351—384, pl. 1).—The author reports in detail the results of fertilizer tests on 23 experiment fields in the Canton of Bern, Switzerland. Thomas meat, superphosphate, potash, calcium carbonate, and liquid manure were applied singly or in various
combinations and amounts. Tables show the results obtained on each of the fields and as a whole, and indicate the percentages of the total potash of the soil which each of 14 field crops was able to abstract from a sandy loam.

The fourth crop since the first application of lime in 1906 indicates that cob lime, ground lime, and ground limestone have continued effective in increasing the crop yield. “Ground limestone has consistently given the largest crop... for the 4 seasons,” as indicated by the average yields of each year. Applications of the 3 forms of lime were followed by 10, 16½, and 25½ cwt. per acre respectively more hay than was secured on the unlimed plat during the 4 seasons. The profit per acre was more than twice as great in case of ground limestone as in case of ground lime, which in turn gave twice the profit secured from cob lime. Botanical analyses of the herbage of the ground limestone plots at the fourth cutting in 1909 showed a higher percentage of Yorkshire Fog (Holcus lanatus) on 2 farms, and a higher percentage of leguminous plants on all 3 farms.

Trials with different grass mixtures in 3-year meadows, 1883-1902, P. Nielsen and E. Lindhard (Tidsskr. Landbr. Plantavl, 17 (1910), No. 3, pp. 367-406).—Trials were conducted at 4 stations to determine the influence of the different species of clovers and grasses in 36 different mixtures on the hay yield.

The results indicate that the selection of legume species is the most important factor in the composition of grass mixtures for 1 to 3 year meadows. If the legume does well, a good hay crop will be obtained; if not, the yield will be small. Under favorable conditions, a good clover and kidney vetch in mixtures will easily equal pure grass mixtures.

Yields of grasses of different species, 1879-1907, P. Nielsen and E. Lindhard (Tidsskr. Landbr. Plantavl, 17 (1910), No. 2, pp. 181-237).—The investigation, which was commenced by the late P. Nielsen in 1879, covers trials with the following grasses: Dactylis glomerata, Lolium perenne, L. italicum, timothy, Avena elatior, Festuca pratensis, F. duriuscula, Alopecurus pratensis, Holcus lanatus, Poa pratensis, and florin grass (Agrostis sp.). The trials were conducted at 5 different experiment stations for a number of years, the seed used being obtained from domestic growers, from other European countries, and from America and Australia.

Seeding lawns and permanent pastures (Ohio Sta. Circ. 106, pp. 2).—This circular suggests methods and grass-seed mixtures for use in seeding lawns and permanent pastures.

Tests of Chile saltpeter under small grains, B. Jancsó (Kisérlet. Közlem., 13 (1910), No. 6, pp. 712-733).—These pages report the results of applications of from 60 to 80 kg. of saltpeter per joch (from 33 to 124 lbs. per acre) to summer crops shortly before sowing and to winter wheat and rye the spring after sowing.

Good results were obtained with the top dressing, except in dry springs, and especially good results were obtained with the winter crop which had been fertilized with phosphorus and potash. Phosphoric acid in the fall followed by phosphoric acid and saltpeter in the spring showed a slightly higher yield.

Some data on work with buckwheat, L. Althausen (Zhur. Opyn. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 6, pp. 801-824).—The author reports the results of work begun in 1908 with red and white flowering strains
of buckwheat. A close relation was found during the seasons of 1908-9 between the yield of grain and straw and the height of the plants.

Schabdar clover, L. Trabut (Bul. Agr. Algérie et Tunisie, 16 (1910), No. 18, pp. 434-436, figs. 2).—The author gives a brief account of tests of Schabdar clover (Trifolium suecorolens) grown from seed obtained from this Department. The tesis seem to indicate that it is well adapted to the rotation of the country and is more resistant on the high plains than berseem (Trifolium alexandrinum).

Fermentation in the hay rick, B. N. Wale and H. C. L. Keable (Jour. Southeast Agr. Col. Wye, 1909, No. 18, pp. 52-55, figs. 2).—Samples of clover hay were weighed at harvest time and later after remaining in hop pockets in the upper, middle, and lower portions of a rick. The average percentage of loss due to fermentation was 15.87. The results of a similar experiment with meadow hay have already been noted (E. S. R., 23, p. 236).

Corn secrets, P. G. Holden (Philadelphia, 1910, pp. 79, figs. 112).—This is a manual of general information for the corn grower. It gives directions for the selection, preparation, and planting of seed and the cultivation of the crop, and suggests means of combating insect enemies. Experimental data already noted (E. S. R., 21, p. 33) are summarized and conclusions drawn from them.

Corn growing in Louisiana, V. L. Roy (Univ. Bul. La. State Univ., n. ser., 11 (1911), No. 2, pp. 51, figs. 25).—Studies of the corn plant and the status of corn growing in Louisiana and the South are accompanied by detailed directions for the production, harvesting, and storing of a corn crop.

The chemical composition of the different parts of the corn plant, I. Weiser (Kisérclet. Közlem., 13 (1910), No. 6, pp. 734-748).—The author reports the results of chemical analyses of the tassel, leaves, husks, the cob and kernels combined, and three divisions of the stalk.

Uniform distribution of the seed in planting compared with a varied distribution (Queensland Agr. Jour., 25 (1910), No. 5, p. 213).—Hogue Yellow Dent corn was planted in hills 3 ft. 8 in. apart each way during 1907-8. Each year 4 plots were planted with an average of 3 kernels per hill variously distributed. The uniform distribution gave slightly better results, but “ordinary variation in rate of dropping found in corn planters will have very little and probably no effect on the yield per acre.”

Cotton-growing experiments in Mexico, C. A. Miller (Daily Cons. and Trade Rpts. [U. S.], 13 (1910), No. 149, p. 1199).—The consul reports that the first cotton crop grown in the vicinity of Columbus, Tamaulipas, yielded a bale or more per acre. The boll weevil caused no trouble but the army worm did some damage. The seed was imported from Georgia.

Cotton crop of Peru, C. A. Miller (Daily Cons. and Trade Rpts. [U. S.], 13 (1910), No. 149, p. 1199).—Estimates by the director of the Lima experimental station are reported on the production and exportation of cotton and cotton seed and its products during 1909-10. The cost of producing native cotton is placed at 2½ cts. per pound. Of the entire crop production, 65 per cent is American Upland, 32½ per cent Peruvian, and 2½ per cent Sea Island and Mitaffi.

Notes on hops, E. S. Salmon (Jour. Southeast Agr. Col. Wye, 1909, No. 18, pp. 337-359, pls. 4).—Earlier work has already been noted (E. S. R., 23, p. 337).

Tables present studies of the relation of the number of seeded and seedless bracteoles to the length of hop. The seeded hops excelled in length by from ½ to ¾ in., although the structure was the same. The increased length “would mean an increase of some 5 or 6 cwt. per acre,” secured by planting male hops which flower at the same time as the general crop. The smaller hops contain
an equal or greater number of bracteoles, the failure to grow out being due to absence of seed.

Seedless hops of the "Størn" variety, similar in structure to the hop produced in the best districts of Germany, were grown in England, but their coarse flavor and poor cropping qualities indicated that they were useless to the English grower. The pollination of a plant of the Saaz (Bavarian) variety by Canterbury Whitebine produced fruit which retained some of the Bavarian flavor of the female parent. The average length of 50 hops was 1 1/2 in., while 3 averaged nearly 2 1/2 in. and 75 bracteoles each.

One (12-burr) lateral springing from either side of the same vine was dusted with pollen and all were kept bagged. Practically all the burr had disappeared from the pollinated hops after 7 days, when the untreated laterals remained in full burr and showed some burr after 16 days.

Three tables present studies of the number of bracteoles, seeds, and length per hop in English and German varieties.

The hop garden (Jour. Southeast. Agr. Col. Wyc. 1909, No. 18, p. 81).—The yield of 9 cwt. of fair quality hops per acre followed an application of 3 cwt. of superphosphate sown around the hills. The garden had been manured in the winter with 30 cwt. of wool waste and in the spring with 6 cwt. of fish guano per acre.

Trials with mangel seeds from large and small roots with and without selection, L. Helweg (Tidsskr. Landbr. Plantearl, 17 (1910), No. 1, pp. 110-112, figs. 4).—The results of trials conducted during the period 1906-1909 are presented and discussed in their practical bearings.

Factors influencing the yield of oats, F. H. Demaree (Missouri Sta. Circ. 45, pp. 89-98).—Discussions of the present status of oats and of the place of the crop in rotation, are followed by directions for its production.

In tests of 16 varieties conducted during 1905-1910 Siberian and Martinsburg produced the highest average yields of 40.18 and 39.83 bu. per acre, among the varieties tested 4 years or more. Red Rust Proof yielding 27.29 bu. per acre in 1908 when all other varieties were ruined by rust. A table states the characteristics of the varieties grown. In sowings of 8, 10, and 12 pk. per acre, it was found that "the weight per bushel and the yield of straw increases with the rate of seeding." The differences in grain yield were slight. Seed treated 10 minutes and 2 hours yielded 10.08 and 8.05 bu. more per acre, respectively, than the untreated seed.

Field trials with oat varieties, 1901-1908, K. Hansen and M. L. Mortensen (Tidsskr. Landbr. Plantearl, 16 (1909), No. 3, pp. 583-702).—Five Danish plant culture stations conducted oat tests during 1901-1908. Detailed information is given as to these trials, and tables state the yield of grain and straw, the type of kernel, the percentage of hulls, and the chemical analyses of the different varieties tested. The varieties are described and their value discussed.

Tenth year's trials with root crops, L. Helweg (Tidsskr. Landbr. Plantearl, 17 (1910), No. 2, pp. 238-270).—Trials were conducted at the Danish plant culture stations with 25 different strains of Barres mangels, 14 of carrots, 5 of mangels, and 4 of raut-bagas, giving results which are presented in tabular form.

The newer fertilizer tests with beet seedlings, L. Sempołowski (Bl. Zuckerriibenbau, 17 (1910), No. 5, pp. 85-88; abs. in Zentbl. Agr. Chem., 39 (1910), No. 12, pp. 860, 861).—The author reports the results of experiments conducted to determine whether on the black soils of southwest Russia artificial fertilizers may be replaced by poultry manure, wood ashes, and similar materials. The entire field received an application of stable manure, and was divided into 10 plats. The fertilizer was applied under the plant.
The higher rates of fertilization produced the higher yields and profits within the limits of the test. The use of poultry manure was followed by higher yields than any other application except a mixture of 2 parts of superphosphate, 6 parts wood ashes, and 2 parts of Chile salt-peter. In net gain it greatly surpassed any other application tested.

The sugar beet industry in Nevada, C. S. Knight (Nevada Sta. Bul. 75, pp. 9-33, figs. 18).—A statement of the climatic and soil requirements of the sugar beet is followed by directions for producing the crop. Especial emphasis is laid on methods of irrigation and extended quotations are given from Farmers' Bulletin 392 (E. S. R., 23, p. 140). Tables give the analyses of beets grown at the station farm in 1910 and in other portions of the State during 1909 and 1910.

[Variety tests and analyses of sugar cane], L. G. Corrie (Ann. Rpt. Queensland Acclim. Soc., 47 (1910), pp. 7-10).—The conditions were unfavorable for high or even average sugar content in any cane, and the 17 highest results obtained from the society's seedlings ranged from 16.02 to 17 per cent of saccharose. The saccharose of 6 West Indian seedlings ranged from 17.32 to 20.26 per cent in 1907, and from 12.52 to 17.40 per cent in 1909. Each variety gave a lower yield in 1909 than in 1907. The standard variety, Rappoe, yielded 13.33 per cent.

The composition of wheat, J. W. Ames (Ohio Sta. Bul. 221, pp. 37, pl. 1).—This bulletin presents analyses of wheat crops grown on soils on which fertility tests have been conducted for 15 years, as previously noted (E. S. R., 20, p. 428), the wheat being grown under various climatic and soil conditions and methods of fertilization. A wide variation was noted in the phosphorus, potassium, and nitrogen contents of the wheat crop analyzed. On unfertilized plats of 2 soils differing as to these elements the composition varied in accordance with that of the soils. Their addition to the soil was followed by an increase in the proportion in which they occurred in the wheat plant. Variation due to seasonal conditions was greater than that resulting from changes in soil composition but those due to soil treatment were "relatively the same for the different seasons."

The addition of phosphorus to a soil deficient in this element increased the amount of phosphorus in the grain. The quantity of potassium was also increased but that of nitrogen decreased. Similar results followed the addition of lime. The use of barnyard manure increased the phosphorus content of the wheat plant to a greater extent than did acid phosphate, bone meal, dissolved bone black, or basic slag, and the use of untreated rock phosphate on a soil rich in nitrogen and potassium markedly increased the phosphorus content of the plant. The nitrogen content of the plant varied with the supply of this element and was also influenced by the supply of phosphorus. The potassium content of the straw varied with that of the soil on which it grew.

The improvement in the quality of wheat exported from the Central Provinces, G. Evans and A. E. Humphries (Cent. Prov. [India], Agr. Dept. Bul. 4, 1910, pp. 1).—The wheats grown in the Central Provinces are of two classes, Pissi or bread wheats and Gehun or macaroni wheats. This paper reports the results of tests of 4 bread wheats of which Raipuri Pissi was strongest but lowest in nitrogen content. Deshi Pissi was most lacking in strength but produced the highest yield, 740 lbs. per acre.

An examination of the seed supply of the Broach District, G. D. Mehta (Dept. Agr. Bombay Bul. 37, 1910, pp. 18).—Tables state the number of seed samples of each species examined and the percentages of purity, germination capacity, and useful seeds found.
Among other general conclusions from the studies, the author indicates that cotton-seed germination is poorer than that of the other seeds, perhaps because bought from local mills; that weevil attack is the greatest source of damage to the samples; and that the presence of hard seed in pulse crops sometimes necessitates a 50 per cent higher rate of sowing. Scratching the surface of such seed with a pin caused it to sprout within a day when placed under conditions otherwise suitable, and a practical machine for the purpose is needed.

[Seed tests and barley analyses], A. Voigt (Jahrb. Hamburg. Wiss. Anst., 26 (1898), pp. 418-444).—Brief descriptive notes state the more important observations made in the examination of different varieties of clover and grass seed, sources of oil and fiber, and by-products.

A report of the results of 12,005 analyses of barley, representing from 100 to 1,000 tons per sample, accompanies data showing that 94.4 per cent of the samples had purity percentages of 93 or higher. Parallel tests were made by different authorities interested, with an average difference of less than 0.523 per cent.

Tables show without comments the results of purity and germination tests of 20,085 seed samples received from 527 sources in 11 European countries.

Report of the seed control station in Lund, 1909, A. Vilke (Frökontroll-anst. Lund Verks. 1909, pp. 39).—Tables and a descriptive text state the results of mechanical analyses of seeds of grasses, legumes, and fiber and other crops. Statistical studies show the frequency of occurrence of the principal weed seeds in seeds of each of the economic varieties analyzed.

The destruction of weeds by chemical means, H. C. Long (Sci. Amer. Sup., 71 (1911), Nos. 1831, pp. 76, 77; 1832, pp. 93, 94, figs. 14).—General discussions of the prevalence, injury, and cooperative destruction of weeds, are followed by a review of work on the destruction of weeds by spraying already noted from various sources. Citations are given to the publications from which the data has been compiled.

Killing weeds with arsenite of soda, E. V. Wilcox (Hawaii Sta. Press Bul. 30, pp. 15).—The author reviews previous work on the use of chemicals for weed destruction and reports studies with a stock solution obtained by boiling together about 2 lbs. sal soda to 1 lb. white arsenic per gallon of water, and diluting with from 15 to 20 parts of water. This solution was used on oil (Stachytarpheta dichotoma), lantana, spurge (Euphorbia peplus), sow thistle, pig-weed, purslane, cockle-burr (Xanthium strumarium), glue (Acacia farnesiana), dodder, Japanese nut-grass, homohono (Commelina nudiflora), crotalaria, and other weeds.

A single application ultimately killed the leaves and stems of all. The effect was usually manifest in 2 or 3 hours but the leaves of the Japanese nut-grass did not turn brown until the second day. The mixture killed alfalfa as well as the dodder with which it was infested. The Hitchcock berry, German ivy, and the nettle (Hesperocentus sandwicensis) were also destroyed by its use.

The author suggests the application of 100 gal. per acre of the diluted mixture. By the use of a 5 gal. knapsack spray, a laborer can spray from 1 to 2 acres per day.

The possibility of danger from the use of arsenite of soda is discussed, with special reference to Hawaiian conditions.

HORTICULTURE.

Experiments in frost protection, A. G. McAdie (Mo. Weather Rev., 38 (1910), No. 12, pp. 1894, 1895, figs. 2).—This article briefly reports experiments which indicate that the efficiency of methods of frost protection by means of
fire pots or similar appliances may be greatly increased by the use of some sort of cover device, and describes a cover suitable for the protection of deciduous fruit trees, and with some modification, for use with vines, garden truck, flowers, and similar crops.

"The cover consists of a reasonably cheap and light-weight material, yet sufficiently tough to withstand out-of-door exposure, and is rainproof. It is essentially a paper cover, and the principle, indeed, is the same as used by many housekeepers and gardeners to protect favorite plants, namely, by covering them with newspapers or cloths. The material can be made in double sheets with an intervening air space, which gives a very high degree of protection. For ordinary use a single layer will suffice. The covers can be made in any size. There is a small central frame of wood, cross braced, to which the paper is tacked. From the central frame flaps of the cloth paper extend, and there are suitable lacing strings provided to bring the ends of the flaps together and also to fasten the cover edges to the tree trunk, so that the cover remains in place should wind arise during the night hours."

Garden management, A. G. B. Bouquet (Oregon Sta. Circ. 11, pp. 8, figs. 3).—This discusses in a popular way some of the important points in the management of a vegetable garden. The phases considered are seeds, soil preparation, arrangement of crops, seed sowing, thinning, fertilization, and transplanting.

Garden profits, E. L. D. Seymour (Garden City, N. Y., 1911, pp. 245, figs. 58).—A popular treatise on vegetable growing, including the management of cold frames and hotbeds, designed primarily for back yard and suburban gardens. In addition to general and specific cultural directions, the records of a number of small, successful gardens are given, together with a working calendar for the year, and chapters on fertilizers, plant diseases and insect pests and their control.

Fertilizers on asparagus, C. P. Close, T. H. White, and W. R. Ballard (Maryland Sta. Bul. 151, pp. 135-146, figs. 2).—A fertilizer experiment with asparagus, planned by H. J. Patterson and W. N. Hutt and conducted continuously from 1905 to 1910 inclusive, is reported. Concise directions are given for starting and caring for an asparagus bed. The experimental bed was started with 1-year-old plants in 1903 on medium loam of good fertility. Comparisons and tests were made of commercial fertilizer versus barnyard manure, different sources of potash, light and heavy applications of kainit, heavy applications of nitrate of soda in spring, heavy applications of salt, manure in different amounts with and without commercial fertilizer, and different times of applying manures and fertilizers. The various treatments, including the results as indicated by the yields and costs of the different treatments, are tabulated and discussed.

Cabbage, L. C. Corbett (U. S. Dept. Agr., Farmers' Bul. 433, pp. 23, figs. 11).—This bulletin contains detailed directions for the culture of cabbage as a truck crop, market-garden crop, and farm crop, including information relative to the soil, fertilizers, starting and transplanting, cultivation, control of insects and diseases, harvesting, varieties, marketing, and storage.

Observations on screening cabbage seed beds, W. J. Schoene (New York State Sta. Bul. 333, pp. 13-34, pls. 2, chart 1).—The observations here recorded were made in order to determine the cost of screening and to show what cabbage growers have accomplished in protecting their seedlings in the manner recommended in Bulletin 301, previously noted (E. S. R., 20, p. 59).

The 2 principal seed bed pests thus dealt with, namely, the turnip flea beetle (Phylloreta vittata) and the cabbage maggot (Pegomya sp.) are briefly considered. The relation of the usual time for growing late cabbage seedlings to
dates of appearance of insects in various stages is illustrated by a chart which shows that in the region considered the period of growth of the plant coincides with the period during which oviposition occurs and the first brood of maggots develop.

The experience of farmers during the past 4 years has shown conclusively that the use of tight frames covered with cheesecloth will entirely prevent injury by the cabbage maggot and that the use of certain grades of cheesecloth will help to prevent injury by the flea beetle. Cloth having from 20 to 30 threads to the inch is to be preferred for the purpose of protecting cabbage seedlings. The extra cost of screening plants in 11 seed beds of 10 different growers was found to range from 6 to 20 cts. per 1,000 plants.

It is stated that plants grown under screens have good roots so that they start quickly when transplanted, while plants grown in the open are liable to suffer a varying amount of root injury even in years when there is only a mild infestation of maggots. "The screened plants are more tender than those not screened, but experience has shown that by removing the cover a week or 10 days before transplanting, the seedlings become sufficiently hardened so that there is very little difference in the growth of the sets in the field." Screening seed beds controls cabbage maggots, F. H. Hall (New York State Sta. Bul. 334, popular ed., pp. 6, figs. 3).—A popular edition of the above.

The home production of onion seed and sets, W. R. Beattie (U. S. Dept. Agr., Farmers' Bul. 434, pp. 24, figs. 12).—In a previous Farmers' Bulletin the culture of onions for the general market was discussed (E. S. R., 21, p. 139). The author here treats in detail of the special methods of culture for the production of onion seed and sets. He points out that whereas both onion seed and sets may be readily grown as a side issue with other lines of farming, there is no large profit to be obtained from the sale of either seed or sets and that the greater profits are obtainable from comparatively small plantings.

Fruit farming in West Kent, C. H. Hooper (Jour. Bd. Agr. [London], 17 (1911), No. 10, pp. 811-815).—A brief general account of the management of fruit orchards in West Kent, giving some data relative to the cost of establishing orchards.

Planting the commercial orchard, J. G. Moore (Wisconsin Sta. Bul. 201, pp. 3-34, figs. 15).—A bulletin taking up in a popular way apple culture with special reference to Wisconsin conditions. General consideration is given to the possibilities of orcharding in Wisconsin and the apple-growing sections of the State. The important cultural phases discussed include the selection of site and soil, the details of planning and planting the orchard, selecting trees for planting including pointers in ordering nursery stock, planting time and distances, top pruning young trees, and varieties for Wisconsin.

Orchard practice, W. J. Green (Ohio Sta. Circ. 108, pp. 8).—This consists of a concise popular discussion of orchard practice. Consideration is given to the details of starting an apple orchard, including a list of varieties suitable for southern and northern Ohio, training, pruning, spraying, thinning, and orchard rejuvenation.

Orchard spraying suggestions for 1911, W. J. Green, A. D. Selby, and H. A. Gossard (Ohio Sta. Circ. 109, pp. 3).—This circular contains advice supplemental to that in Bulletin 199 previously noted (E. S. R., 20, p. 1055).
Experiment Station Record.

Orchard sprays and spraying, A. B. Cordley and H. S. Jackson (Oregon Sta. Circ. 13, pp. 3-16).—Directions are given for the preparation and application of insecticides and fungicides in combating the insect enemies and fungus diseases of the apple, pear, peach, plum, prune, and cherry.

Report on inspection of orchard irrigation plants, E. Krüger (Deut. Obstbau Ztg., 1911, No. 8, pp. 129-134, figs. 7).—The irrigation of a number of orchards in Germany is described.

Breeding ever-bearing strawberries, C. F. Gardner (Nat. Hort., 3 (1911), No. 6, pp. 9, 10).—A short account of the author's work in breeding ever-bearing strawberries. One variety particularly which gives promise of bearing continuously from June to November is being further developed.

On the use of insecticides in viticulture, L. Moreau and E. Vinet (Compt. Rend., Acad. Sci. [Paris], 151 (1910), No. 23, pp. 1068-1070).—Experiments made at the Angers enological station to determine the amount of lead arsenate retained by grapes when applied for the first and second generations of the cochylis moth are here reported. See also a previous note (E. S. R., 24, p. 188).

The use of lead arsenate in viticulture and the consumption of table grapes and raisins, L. Moreau and E. Vinet (Compt. Rend., Acad. Sci. [Paris], 151 (1910), No. 24, pp. 1137, 1138).—A continuation of the investigations above noted, in which the authors report the results of analyses made of the berries and stems of grapes sprayed twice prior to blooming (May 31 and June 14) with arsenate of lead, and also of those to which a third application was made (August 6) after blooming.

In analyses made August 6 of the grapes that had received 2 applications, 0.86 mg. of arsenate of lead to 100 gm. weight was found in the berries and 4.86 mg. in the stems; none was found in the berries but 0.62 mg. in the stems of grapes harvested October 15. In analyses made August 6, directly following the third application, 10.60 mg. of arsenate of lead to 100 gm. weight was found in the berries and 28.33 mg. in the stems; 0.40 mg. was found in the berries in collections made at the time of vintage on October 27 and 5.51 mg. in the stems.

The amount of arsenic in Algerian grapes, P. Fetel (Bull. Agr. Algérie et Tunisie, 16 (1910), No. 18, pp. 430-434).—With a view to providing data regarding the use of arsenic sprays, grapes were analyzed for the presence of this element and in the neighborhood of 0.5 mg. per kilogram of fruit was found.

Consideration is given to the botany, anatomy, and varieties of the banana, banana soils, including physical and chemical analyses of various soil types, cultivation and preparation of land, planting and planting distances, irrigation and drainage, cultivation after planting, treatment of suckers, pruning leaves, harvesting, replanting, and data on the cost of cultivation, receipts, areas under bananas, and exports.

Popular garden flowers, W. P. Wright (London, 1911, pp. XI+376, pls. 54).—In the present work the author deals with the most important garden flowers, relative to their history, the origin and pronunciation of their names, their position in literature and folklore, value as modern garden plants, and culture, and the best varieties. With such plants as carnations, chrysanthemums, and roses, a summary of cultural operations in the form of a monthly calendar is given.

The book of roses, L. Durand (London and New York, 1911, pp. VII+101, pls. 16).—A popular work containing general directions for propagating and growing roses, together with specific information relative to the culture of roses.
of various types. Chapters are also included on exhibiting roses and the enemies of the rose. A list of good roses for garden cultivation is appended.

Injuries to the rose by animals, M. Schwartta (In Rosenkrankheiten und Rosenfeinde. Jena, 1910, pp. 35–39).—Some 50 species of animals are briefly described and tabulated according to the parts of the plant that they injure. Remedial measures are briefly noted.

Cut-flower industry in southern France, F. M. Mansfield (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 87, pp. 193–200, fig. 1).—An account of the cut-flower industry of southern France, with special reference to methods of preparing the flowers for market and facilities for expeditious and economical distribution of the product.

FORESTRY.

The supplement contains an addition of some 20 species new to the book, together with a systematic index of the names of trees of the eastern United States, including the botanical names according to A. Gray and C. S. Sargent.

The hardy catalpa in Iowa, C. A. Scott (Iowa Sta. Bul. 120, pp. 309–325, figs. 5).—This bulletin contains directions for establishing and caring for plantations of hardy catalpa (Catalpa speciosa), discussing the range of successful growth, form and size, selection of species, propagation from seeds, planting stock, soil requirements, preparation of planting site, time of planting, spacing, cultivation and care of plantation, protection against rabbits, cutting back, fungus diseases, length of rotation, second crop, time of cutting, seasoning, and durability of catalpa wood.

Nearly all the hardy catalpa plantations in the State have been studied by the forestry section of the station. A large majority of these plantations have proved successful, and the results obtained on some of them are given. The gross annual return per acre on the plantations studied varied from $10.77 to $20.34. Eighteen-year-old trees that have been properly cared for will yield from 2,000 to 2,500 posts to the acre.

The hardy catalpa is of special importance in Iowa for the production of fence posts. The annual destruction of the late growing terminal shoots at the approach of winter, coupled with the liability of older trees to fungus attacks, results in very crooked and, generally, diseased poles. Hardy catalpa posts which have not become infected by fungi before cutting and which are properly seasoned rank next to Osage orange and red cedar in durability. They season best if cut in November or December, but if a second crop is desired from sprout reproduction, the first cutting should be made in February or March. The most common cause of failure with catalpas is attributed to the substitution of the common catalpa (Catalpa catalpa), which is not hardy enough for Iowa. It can be distinguished from the hardy species by differences in the bark and seeds.

The oak: Its natural history, antiquity, and folklore, C. Moseley (London, 1910, pp. IX+126, pls. 8).—This popular work deals largely with the history of the oak in the British Isles.

Some notes on jack pine (Pinus divaricata) in western Ontario, L. M. Ellis (Forestry Quart., 9 (1911). No. 1, pp. 1–14, pl. 1).—These notes, which are
based largely on the author's field investigations, discuss distribution and association, habitat, characteristics, silvicultural requirements, and rate of growth of jack pine. Tabular data showing composition of type stands, taper of logs on different grades of soil, height, diameter, and volume measurements, including rate of growth and yield of ties under average soil conditions, are also given.

The rubber plants of western and southern Madagascar, H. Jumelle and H. Perrier (Agr. Prat. Pays Chauds, 11 (1911), No. 96, pp. 177–193).—An account of the rubber plants in western and southern Madagascar with special reference to their geographic distribution and exploitation. Most of the plants noted have been previously described (E. S. R., 24, p. 245).

The rubber country of the Amazon, H. C. Pearson (New York, 1911, pp. X+228, pl. 1, figs. 175, maps 5).—A detailed description of the great rubber industry of the Amazon Valley, which comprises the Brazilian States of Pará, Amazonas, and Matto Grosso, the Territory of the Acre, the Montaña of Peru and Bolivia, and the southern portions of Colombia and Venezuela.

Fixation of the dunes on the coast of Jutland, W. J. Morrill (Forestry Quart., 9 (1911), No. 1, pp. 62–67).—A description of the methods employed in Denmark to stop the shifting of sands, the subject matter being adapted from an article by J. Givskov.

Grain and texture in wood, S. J. Record (Forestry Quart., 9 (1911), No. 1, pp. 22–25).—A discussion of the terms “grain” and “texture” in relation to their use in forestry.

Strength of ties treated with crude oil (Engin. Rec., 63 (1911), No. 12, p. 335).—Results are given and discussed of a test conducted by W. K. Hatt of Purdue University to determine the effect of crude-oil treatment on the strength of loblolly pine, shortleaf pine, and red gum ties. The spike-holding power of the ties appears to be materially decreased by the crude oil treatment.

Forest protection, C. A. Schenck (Asheville, N. C., 1909, pp. 159).—This is a guide to lectures on forest protection delivered at the Biltmore Forest School. The material is presented under the general headings of protection against organic and inorganic nature. Under the former heading are discussed protection against man, animals, and plants, and under the latter heading consideration is given to adverse climatic influences, storms, erosion, sand drifts, and noxious gases.

Purchase of land under the Weeks law in the southern Appalachian and White Mountains (U. S. Dept. Agr., Forest Serv. [Pamphlet], 1911, pp. 9).—The purposes and text are given of the recent federal law authorizing the purchase of lands for preserving the watersheds and conserving the navigability of streams (E. S. R., 23, p. 498). The classes of land desired and the procedure in making selections and purchase, as well as the areas within which proposals for sale are at present invited, are indicated.

Some facts on forestry conditions in Sweden, C. Metzger, trans. by M. H. Foerster (Forestry Quart., 9 (1911), No. 1, pp. 35–58).—A translation of the author’s article, previously noted (E. S. R., 23, p. 147).

The Swedish forest conservation law, B. E. Fernow (Forestry Quart., 9 (1911), No. 1, pp. 59–61).—A brief review of the work of the county conserva-
tion boards, organized in Sweden under the above-named law in 1905, in connection with the policy of influencing private forest management.

**Report on Cyprus forestry, D. E. Hutchins** (*London, 1909, pp. 93, pls. 20, map 1*).—This report includes a descriptive account of the forests of Cyprus and describes the progress made in forest management, methods of exploitation, forest produce, and similar matters.

**Progress report on forest administration in the Punjab for 1909–10, C. P. Fisher** (*Rpt. Forest Admin. Punjab, 1909–10, pp. 21††L†*).—This is the usual report relative to the constitution and management of the state forests in the Punjab, including a financial statement for the year. The more important data relative to areas, forest operations, exploitation, yields, revenues, expenditures, etc., are appended in tabular form.

**Report on the forests and forestry problems in Sierra Leone, A. H. Unwin** (*London, 1909, pp. 5‡, pls. 21*).—In addition to a general description of the principal forests in Sierra Leone, notes are given on the species of trees found there, the present condition of the forest, forest products, and exploitation, with suggestions relative to future management. A report on the proposed forest reserves for the Imperial War Department is also included. Tabular data are given listing the indigenous trees in the Colony and Protectorate of Sierra Leone, timbers used by the War Department, imports and exports of forest produce, proposed timber fees and girth limits, and estimates of revenues and expenditures.

**A bibliography of forest literature for the year 1910** (*Skogsvardsför. Tidskr., 1911, Puckafld., No. 3, pp. 148–164*).—A bibliography is given of the important European and American literature on forestry and allied subjects issued during 1910.

### DISEASES OF PLANTS.

**Cultures of some heterocystous rusts, W. P. Fraser** (*Mycologia, 3 (1911), No. 2, pp. 67–74*).—Successful cultures are reported as follows: Telutospores of *Melampsorosiis cassandrae* from *Chamaeaphne calyculata* producedaecidia of *Peridermium consimile* on *Picea rubra*; telutospores of *M. abietina* from *Ledum greenlandicum* producedaecidia of *Peridermium abietinum* on *Picea rubra*; teluto- spores of *M. ledicola* from *Ledum* sp. producedaecidia of *Peridermium decolorans* on *Picea canadensis*; telutospores of *Uromyces peckianus* from *Distichlis spicata* producedaecidia on *Atriplex patula hastata* and *Chenopodium album*.

In addition to the cultures noted, the alternate stages of these rusts were found constantly associated on their corresponding hosts in the open fields and woods. Also, *M. pyrole* was found associated with *Peridermium conorum-piceae*, the uredo and telutospore stages on *Pyrolo americana* and *P. elliptica*, and the aecidial stage on the young pistillate cones of *Picea mariana*. The aecidial stage of *Calyptospora columnaris* is reported as common on young plants of *Abies balsamea*.

**On some parasitic Plasmodiophoraceae, R. Maire and A. Tison** (*Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 4, pp. 206–208*).—The authors propose and describe a new genus, *Ligniera*, and two new species, *L. radicalis* and *L. verrucosa*, for that group of the parasitic Plasmodiophoraceae which do not produce hypertrophy of the affected tissues of the host.

*Sorosphora junici* is also transferred to this new genus as *L. junici*.
Take-all (Ophiobolus graminis). G. L. Sutton (Agr. Gaz. N. S. Wales, 22 (1911), No. 2, pp. 161-163).—The characteristics of this disease, its prevalence, and the damage done by it, together with suggestions as to its control, are given. See also a previous note (E. S. R., 24, p. 551).

The relation of crown gall to legume inoculation, K. F. Kellerman (U. S. Dept. Agr., Bur. Plant Indus. Circ. 76, pp. 6, pl. 1).—Attention is called to the presence on the roots of alfalfa, crimson clover, and alsike clover of tumors somewhat resembling normal nitrogen-fixing nodules, but in reality galls of the crown-gall organism (Bacterium tumefaciens). The differences, which are here described, between these tumors and nitrogen-fixing nodules are sufficiently typical to be easily recognized by an experienced observer, both by their external appearance and by the use of special culture media. The author advises that great care should be taken in using soil or cultures for inoculating legumes in regions which may eventually be used for sugar beets or for orchards.

A foot rot of asparagus, R. Farneti (Riv. Patol. Veg., 4 (1910), No. 18, pp. 273-277).—Attention is called to a serious disease of asparagus in Liguria, which causes a rotting of the younger shoots at their point of attachment to the rhizome, resulting finally in their death and separation from the rhizome. An examination of the roots of diseased plants showed the presence of black, globular perithecia, which belong to Zopfia rhizophila (Perisporiaceae).

The destruction of all diseased plants by burning, and the disinfection of the asparagus beds with carbon bisulphid, are recommended.

Wilt disease of cotton in Georgia and its control; cotton anthracnose, A. C. Lewis (Ga. Bd. Ent. Bul. 34, 1911, pp. 31, pls. 3, figs. 10).—The author gives notes on the history, distribution, annual losses, symptoms, and cause of cotton wilt (Vecosmospora vasinfecta), together with a report on experiments from 1905 to 1910 with different fertilizers, fungicides, and resistant varieties of cotton in combating the wilt. The fertilizers and fungicides proved to be of no value in controlling the disease, but by planting wilt-resistant varieties of cotton, together with a proper crop rotation, good yields were secured and very little of the cotton died from the wilt. The varieties of cotton recommended as wilt-resistant are Dillon, Dixie, Modela, Grant, and an unnamed hybrid. For crop rotation, corn, oats, wheat, rye, Iron cowpea, velvet bean, and peanuts are suggested, as these crops are resistant to both the fungus and nematode.

A discussion is also presented of the symptoms and cause of cotton anthracnose, and the author gives the results of tests as to the resistance to this disease of various varieties of cotton. The disease is said to be carried over in the seed, and since at present no practical method is known of treating the seed to kill the fungus spores, rotation of crops and the planting of varieties which are more or less resistant to the disease, such as Sistrum, Schley, and Modella, are advised.

Wart disease of the potato, W. Cuthbertson (Gard. Chron., 3. ser., 49 (1911), No. 1261, pp. 122, 123).—Attention is called to the fact that all varieties of the Up-to-date type, which are the most resistant to the late blight (Phytophthora infestans), are the most susceptible to the wart disease (Synchytrium endobioticum), while some varieties of the Abundance type which succumb quickest to the late blight are resistant to the wart disease. Varieties of the Langworthy type are resistant to both diseases.

These observations are based on the results of tests with different varieties of potatoes resistant to the wart disease as reported in a recent bulletin from the Harper-Adams Agricultural College (E. S. R., 24, p. 449).

The rottin of root crops during the winter of 1908-9, F. K. Ravn (Tidsskr. Landbr. Planteavl, 17 (1910), No. 1, pp. 143-162, figs. 4).—The
author presents a study of the causes of a general rotting of root crops (mangels and ruta-bagas) on Danish farms during the winter of 1908-9.

**Fungus diseases of the apple,** Edna F. McCormack (Ann. Rpt. State Ent. Ind., 3 (1909-10), pp. 128-165, figs. 29).—The author describes the symptoms of the common diseases of the apple in Indiana, and gives the measures to be used in combating them.

Observations on the susceptibility of different kinds of cherries to the Botrytis fungus (Sclerotinia cinerea), G. Köck (Ztschr. Landw. Versuchsw. Österr., 13 (1910), No. 11, pp. 889, 890).—It is claimed that the apparent immunity of certain varieties of cherries to the attack of this fungus is due to the fact that their time of blossoming for a given locality does not coincide with the weather conditions favorable for the propagation of this disease, while other varieties which are apparently susceptible have their blooming period coincident with the weather conditions suitable for infection by the Botrytis rot (S. cinerea), and therefore are often severely attacked by the fungus.

**Contribution to the biology of the grape mildew,** J. Laurent (Rev. Sci. [Paris], 49 (1911), I, No. 9, pp. 267-272).—The author discusses the variation in virulence of the mildew and the relative susceptibility and immunity of certain varieties of the grape to the disease. Attention is again called to the results of experiments (E. S. R., 24, p. 650) in which the degree of sap concentration seems to indicate the immunity to the disease which a given variety of grapes may possess, the higher the molecular concentration the greater being the resistance.

**[Decree concerning the exportation of diseased fruit trees from Holland]** (Bul. Mens. Off. Reuseig. Agr. [Paris], 10 (1911), No. 1, pp. 39-44).—The text is given of a decree issued in Holland in 1909 concerning the inspection of all fruit trees offered for export. A certificate is required showing the nature of the shipment, where grown, the point of distribution, and a statement from the state entomologist and phytologist of Holland that the plants have been inspected and found free from the San José scale, peach yellows, rossette, or other pests liable to dissemination on nursery stock.

**Brown root disease,** T. Petch (Cires. and Agr. Jour. Roy. Bot. Gard. Ceylon, 5 (1919), No. 6, pp. 47-54, pls. 3).—The symptoms, cause, and methods of infection of this disease are given. It attacks many kinds of plants, such as Hevea, cacao, tea, dadap, Castilla, Caravonica cotton, capamhor, and Brunfelsia americana, and is characterized by an encrustation of the roots, especially the tap root, with a mass of sand, earth, and small stones to a thickness of 3 to 4 mm.; this crust, as a rule, extends up the stem for several inches.

Recently the fungus concerned has been certainly identified as Hymenosphaeria noxia by its fructifications, which form a thin, dark brown crust on the base of the stems. As the fructifications of this fungus appear only on stems or stumps dead for a long time, the spread of the disease from one living plant to the next is due to the mycelium spreading from root to root of adjacent plants where the roots are in contact.

In Ceylon the disease attacks cacao and spreads from it to the Hevea trees which have been interplanted with cacao. The remedial treatment consists of the removal and burning of the dead trees and their roots, and in case of young Hevea planted on old cacao land all cacao stumps should be dug out at once.

A similar jungle disease attributed to H. rigidula and found on several species of trees is also discussed, and the peculiar, honeycomb-like character of the diseased wood is figured.

The Gloeosporium rot of bananas and a Phyllosticta leaf spot of ivy, R. Laubert (Gartenflora, 59 (1910), No. 19, pp. 409-415, pl. 1, figs. 2).—Attention
is called to a rott of bananas very common on the fruit offered for sale in the markets. This is probably due to G. musarum, a fungus closely related to G. fructigenum, the cause of bitter rott of apples.

A description is given of a leaf spot of ivy produced by P. hedericola.

Cacao and Hevea canker, T. Petch (Cires. and Agr. Jour. Roy. Bot. Gard. Ceylon, 5 (1910), No. 13, pp. 142–180).—After a general discussion of the literature bearing on the cacao pod rot and canker, the author gives the results of inoculation experiments with the cacao Phytophthora on the pods and stems of cacao and Hevea. A description of the fungus (P. faberi), symptoms of the disease on cacao and Hevea, and methods of treatment are also given.

Both stem canker and pod rott were produced by introducing Phytophthora cultures into the pods and stems of cacao and Hevea, while inoculations with various species of Nectria on both cacao and Hevea gave negative results. The author, therefore, concludes that stem canker and fruit rott of both cacao and Hevea are due to the same organism, P. faberi.

The treatment of cacao canker and pod disease comes under 4 heads, viz., excision of diseased tissues, collection of diseased pods, removal of shade and spraying. The location and character of the disease, whether on the stems or pods, determine which of these remedies should be used, as well as the type of the plantation, whether heavily shaded or interplanted with Hevea. The results of various spraying experiments are given, but the cost in most cases seemed prohibitive compared to the results obtained.

The fungus develops freely on pieces of jak wood and on decaying jak stumps; these should, therefore, be kept out of Hevea plantations. Dead Hevea trees should be dug up with as much of the roots as possible and burned. Any neighboring stumps, especially jak stumps, and all pieces of woods and roots should also be burned; and since the disease can be spread by rhizomorphs through the soil to adjacent trees, the affected area should be isolated by trenches about 1 ft. deep, and the inclosed ground should be dug up and treated with quicklime.

Pink disease of Para rubber and Bordeaux mixture, R. D. Anstead (Planters' Chron., 6 (1911), No. 8, pp. 98–101).—In the experiments reported, over 200,000 trees were treated for pink disease (Corticiwm javanicum) with a 6:4:45 Bordeaux mixture to which some type of sticker had been added. The mixture was applied with a brush to the trunk, special attention being given to the forks and whorls of branches, where it was well rubbed in.

The best time for the first application was found to be during May and June, while a second application seemed to be unnecessary. On one plantation the treated area showed only 0.56 per cent of the disease, or less than 1 tree per acre, while the untreated trees gave 1.34 per cent, or 2 diseased trees per acre. Practically similar results were obtained on the other plantations. It is stated that if every tree is properly treated with this mixture, there will be no cases of the disease.

The copper blight of tea, F. J. F. Shaw (Agr. Jour. India, 6 (1911), No. 1, pp. 78, 79).—The symptoms of this disease, which is attributed to Lastadia theae, are described, and its probable identity with a similar blight previously reported from Assam is suggested.

The fungus, which was found on dried leaves from Dooars, produces small, irregular, copper-colored spots on the upper surface of the leaves. Later, the discoloration extends entirely through the leaf, appearing on the under
surface as a yellowish brown patch, while the upper surface is now of a grayish color. During the earlier stages the diseased areas are covered with minute black spots, due to the presence of pycnidia situated just below the epidermis of the leaf. The blight spreads with extreme rapidity and attacks only the older leaves.

Plucking and burning the diseased leaves and spraying with Bordeaux mixture are suggested as possible remedies.

**Root diseases of tea**, T. Petch (Circs. and Agr. Jour. Roy. Bot. Gard. Ceylon, 5 (1910), No. 11, pp. 95–114, pls. 2).—Five root diseases of tea have been investigated, and are here listed in order of prevalence: *Ustulina zonata*, *Hymenochara noria*, *Poria hypolaterita*, *Botryodiplodia theobromae*, and *Rosellinia bothrina*. The distinguishing marks and symptoms of each disease are given, and methods of treatment suggested.

**Root diseases of Acacia decurrens**, T. Petch (Circs. and Agr. Jour. Roy. Bot. Gard. Ceylon, 5 (1910), No. 10, pp. 89–94, pls. 3).—The author describes two root diseases of this tree. One, due to *Armillaria fuscipes*, causes the death of trees 15 months old or over which are used as windbreaks in tea plantations, but the fungus apparently does not attack the tea; the other, *Fomes australis*, a common jungle fungus, attacks old trees of *A. decurrens*, at Hakgala, slowly and gradually killing them.

Uprooting and burning the diseased trees is suggested as a probable remedy for checking further dissemination.

**The spruce scab** (*Lophodermium macrosporum*), E. Mer (Bul. Soc. Sci. Nancy, 3, ser. 11 (1910), No. 1, pp. 1–59).—The first and major portion of this paper is a reprint of a previous article on this subject (E. S. R., 24, p. 453) by the same author, while the second and concluding part discusses the damage done by this fungus and suggests preventive and curative measures (E. S. R., 24, p. 251).

**Some new parasitic fungi of ornamental plants**, G. Trincheri (Bul. Orto Bot. R. Univ. Napoli, 2 (1910), No. 4, pp. 495–504).—In addition to 4 species previously noted (E. S. R., 23, p. 355) the author describes as new *Macrophoma dyckiae* on the scapes of *Dyckia sulphurica*, *Ascochyla havorthiae* on the scapes of *Havorthia tortuosa*, and *Chatomella gasteriae* on the scapes of *Gasteria fuscopunctata*.

**Spray injury induced by lime-sulphur preparations**, E. Wallace (New York Cornell Stai. Bul. 288, pp. 105–137, pls. 4).—This bulletin gives the results of experiments with lime-sulphur mixtures, arsenical preparations, and combinations of the two on fruit and foliage injury to fruit trees, especially apples and peaches.

It was found that the method of application is a very important factor, as overdrenching of the trees seemed likely to cause burning of the foliage. Arsenite of lime, arsenite of soda, or Paris green is likely to cause serious foliage injury, while arsenate of lead decreased to some extent the caustic properties of lime-sulphur sprays and seemed to be the only arsenical that could be used with the lime sulphur on apple foliage. However, lime-sulphur and arsenate of lead mixture when applied with a gas sprayer may produce some injury to apple foliage, and certainly caused serious defoliation of peach trees in the tests made.

The addition of lime or the retention of the sediment of the lime-sulphur solution affected very little the amount of foliage injury. Precipitation of lime-sulphur solution alone by the carbon dioxide of the gas sprayer prevented any caustic action on peach foliage, even at a strength of 1:30, and with no apparent diminution of its fungicidal properties. Infection of apple leaves with the scab fungus previous to the application of the spray was one of the
most common causes of spray injury, by admitting the spray material to the interior tissues of the leaf.

Varietal susceptibility seems important, at least with pears, as Duchess was more susceptible to foliage injury than any of the other varieties. A commercial brand of arsenate of lead used alone caused foliage injury to appear sooner on peaches than when used in combination with lime sulphur 1:150. The russetting of apples from lime-sulphur sprays is very rare and of minor importance.

The injurious action of lime sulphur is claimed to be fundamentally different from that of Bordeaux mixture. The Bordeaux mixture injury usually does not occur at once, but appears under certain atmospheric conditions, while the lime-sulphur injury is initiated before the solution dries on the trees.

**Lime sulphur as a summer spray**, E. Wallace *(New York Cornell Sta. Bul. 289, pp. 141-162, figs. 9).*—The general results are given of investigations of lime sulphur as a summer spray, conducted during 1909-10 by the author as a fellow on the Niagara Sprayer Company Fellowship in the Department of Plant Pathology of Cornell University (E. S. R., 22, pp. 650, 652).

It is claimed as a result of these experiments, which extended throughout both a dry and a wet season, that lime-sulphur solution properly used in combination with lead arsenate is as effective in controlling apple scab as Bordeaux mixture. Home-boiled and commercial preparations of lime sulphur diluted 1:30 and 1:40 combined with lead arsenate, and Bordeaux mixture 3:3:50 with lead arsenate, were found about equally effective in controlling the scab. It is claimed that the addition of lead arsenate to the lime-sulphur sprays increased the fungicidal value of the lime-sulphur mixture about 50 per cent.

According to the laboratory tests, sediment from heavy grade Niagara lime sulphur with a 2:30 dilution proved to have about half as much fungicidal value as the solution volume for volume, but varied with the magnesium content of the lime used in the spray. Magnesium oxid, according to laboratory tests, was found to have considerable fungicidal value.

On apple trees the scab was reduced from 79.4 per cent to 29.5 per cent by a 1:30 lime-sulphur spray, and to 10.9 per cent when arsenate of lead was added to the spray. On pear trees 3 applications of a 1:40 solution of lime sulphur reduced the early pedicel infection of 73 per cent to 13 per cent, while the same concentration of lime sulphur with lead arsenate reduced it to 6 per cent with only one application.

Comparisons of properly prepared home-boiled concentrated and commercial lime-sulphur sprays showed that the control was practically equal in each case. It is claimed that the precipitation of the sulphur present in the lime-sulphur solutions by means of carbon-dioxide gas did not affect the fungicidal properties of the spray, at least when used for brown rot on Atlanta peaches, where it reduced the rot from 45 per cent to 1.5 per cent with 2 applications of a 1:30 lime-sulphur solution alone, and to 6.5 per cent by one application. When the lime-sulphur and lead-arsenate spray was applied with the gas sprayer, serious injury to the foliage of the peach trees resulted, apparently due to the action of the gas on the arsenical present; on apples this caused only slight injury in the case tested.

The first spraying before the blossoms open is chiefly instrumental in giving a better set of fruit when the early season favors scab infection, and in preventing foliage injury from later applications by keeping the fungus off the leaves. The second application after the blossoms fall is usually the most important one in keeping the fruit free from scab. The third application two weeks later seemed from the experiments to be of little importance during 1909 and 1910.
For controlling apple scab, 4 applications of a 1:40 lime-sulphur solution to which 2 lbs. of lead arsenate has been added is advised. The first application should come just before the blossoms open, the second after the blossoms fall, the third two weeks later, and the fourth 9 weeks after the blossoms fall. For pear scab, the number of applications will have to be increased in orchards where the scab fungus has become well established on the twigs, as the fungus in these infected twigs continues to grow throughout the season, constantly producing a crop of spores for the continuous infection of leaves and fruit.

Studies of the fungicidal value of lime-sulphur preparations, E. Wallace, F. M. Blodgett, and L. R. Hesler (New York Cornell Sta. Bul. 290, pp. 167-207, pl. 1, figs. 2).—A report is made on the results of experiments for testing the fungicidal value of different strengths of lime-sulphur mixtures.

The method of testing the fungicide was as follows: Glass slides were sprayed with the material to be tested and subjected to atmospheric conditions until the coating of spray had thoroughly dried; then drops of water containing viable spores of the fungus were placed on the sprayed slides, and also as checks on unsprayed slides. The number of spores which germinated on the slides was used as a criterion of the germicidal power of the spray under consideration.

Lime-sulphur solutions, at a strength safe for foliage, were found by both field and laboratory tests to be only fairly effective as a fungicide. In general, a stronger concentration was required to prevent germination of conidia of scab (Venturia inaequalis) than those of brown rot (Sclerotinia fructigena), and still stronger for apple canker (Sphaeroptis malorum). Arsenate of lead used alone seemed to have some fungicidal value which showed up better in the field than in the laboratory tests, probably due to its adhesive properties which kept the surface of the host coated with the poison so that the fungus hyphae could not penetrate the leaf. The addition of arsenate of lead to the lime-sulphur material increased the fungicidal value of the mixture (see above). The action of carbon dioxide on the lime sulphur, although entirely changing its chemical composition, did not materially affect its fungicidal value. The addition of lime or of iron sulphate to the lime-sulphur solution seemed to increase its efficiency slightly. When arsenate of lead was added to the iron-sulphate lime-sulphur mixture, the increase in efficiency observed when arsenic was added to the lime-sulphur mixture did not occur.

The spore itself seems to be active in bringing into solution small quantities of the fungicide, which in turn prevents germination.

The preparation of copper sprays, G. Chappaz (Prog. Agr. et Vit. (Ed. l’Est-Centre), 32 (1911), No. 10, pp. 289-294).—The author gives the formulas and describes the methods of preparing the various copper sprays which are used in combating fungus diseases of the orchard.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Seed-eating mammals in relation to reforestation, N. Dearborn (U. S. Dept. Agr., Bur. Biol. Survey Circ. 78, pp. 5, figs. 3).—This circular reports the results to date of investigations conducted by the Biological Survey in cooperation with the Forest Service for the purpose of devising methods of protecting seeds from destructive rodents. It is stated that the protection of newly planted seeds from the attacks of mice, chipmunks, ground squirrels, and other rodents, the depredations from which collectively continue the year through, furnish one of the most serious problems connected with the reforestation of treeless areas within the National Forests.

In exhaustive trappings on a half acre containing 2,000 seed spots, 3 chipmunks and 11 white-footed mice were secured which in the course of 3 days
EXPERIMENT STATION RECORD.

had pilfered 70 per cent of the seed. One of the chipmunks was seen to visit 38 seed spots in 4 minutes. In a reforestation experiment in the Black Hills by the Forest Service, from 30 to 70 per cent of the seed was destroyed by chipmunks and mice within 6 days after planting. The chief seed eaters concerned are Say's ground squirrel (Callosphercnophia! lateralis), thirty-one-line ground squirrel (Citellus tridecemlineatus pallidus), Rocky Mountain chipmunk (Eutamias quadricivitatus), and white-footed mouse (Peromyscus maniculatus rufus).

Protective coatings proved inefficient and the use of poisoned bait is recommended, preferably before seeding. Two formulas are given with directions for the preparation of poisoned bait, the first of which consists of wheat 1 bu., water 1 qt., starch 2 tablespoonsfuls, saccharine 2 teaspoonfuls, and strychnia (pulverized) 2 oz.; the second of rolled oats 25 qt., strychnia (pulverized) 1 oz., saccharine 1 teaspoonful, and water 6 qt. The second is a much more attractive bait and one much easier to prepare, but the cost of the rolled oats considerably exceeds that of wheat.

Ordinarily in distributing poisoned wheat about 20 kernels should be dropped every 3 or 4 ft. along parallel lines about 5 yds. apart, an extra quantity being left under logs and shelving boulders. At this rate a bushel of wheat is sufficient for about 40 acres. Poisoned bait may be protected from rain and guarded from birds or poultry by placing it under pieces of bark or small piles of stones. A sack for distributing poisoned grain, made of denim or other strong cloth with a shoulder strap and a narrow wooden bottom fitted with a simple dropping device, is described and the details relating to its structure made clear by figures.

The mammals of Europe, E. L. Trouessart (Faune des Mammifères d'Europe, Berlin, 1910, pp. XVII+266; rev. in Nature [London], 85 (1910), No. 2140, pp. 3, 4).—This is a descriptive catalogue of the mammals of Europe. As regards the distribution of the European fauna, the author recognizes four distinct areas, namely, Central European, Arctic, Eastern or Steppe, and African or Mediterranean.

Our vanishing shorebirds, W. L. McAtee (U. S. Dept. Agr., Bur. Biol. Survey Circ. 79, pp. 9, figs. 3).—This circular calls attention to the fact that shorebirds have been hunted until only a remnant of their once vast numbers is left. Their limited powers of reproduction, coupled with the natural vicissitudes of the breeding period make their increase slow and peculiarly expose them to danger of extermination. Emphasis is placed upon the great need of better protection, especially in view of their economic importance, which is discussed.

Reptiles of the world, R. L. Ditmars (New York, 1910, pp. XI+373, pls. 90).—The author gives in a popular manner a general survey of the reptiles of the world. It is illustrated by plates from photographs taken from life.

A list of insects affecting stored cereals (pp. 1-7).—Seventy-six species of insects affecting stored cereals and cereal products are listed, together with their common names, brief references to their literature, and notes on their feeding habits.

The Mexican grain beetle (Pharaxonotha kirsch) (pp. 8-13).—While not permanently established in this country, the Mexican grain beetle has come repeatedly under the author's observation. It was first observed infesting stored grain in the foreign exhibits at the World's Columbian Exposition at
Chicago, in 1893, at which time it was practically unknown to American scientists. This beetle has since been received in stored corn from the State of Oaxaca, Mexico. The original generic and specific descriptions are reproduced and descriptions given of its immature stages. The literature relating to the species is considered in connection with a bibliography of 10 titles.

Adults placed in a rearing jar of fresh meal, with slices of raw potato to furnish additional moisture, and kept in a cool room showed conclusively that they were able to withstand the average temperature of an ordinary mill, warehouse, or granary of a latitude such as that of the District of Columbia. It is stated that the beetles are much more active than the meal-feeding tenebrionids. At summer temperature the life cycle from egg to adult was found to be passed in 32 days.

The Siamese grain beetle (Lophocateres pusillus) (pp. 11–18).—This beetle was found for the first time in rice and other cereal exhibits from Siam, Liberia, and Ceylon, at the World's Columbian Exposition in 1893. It has since been found to be established at Charleston, S. C., and Houston, Galveston, and Brownsville, Tex., and has been received in grain from New Braunfels, Tex., Peru, Guatemala, Java, Siam, and in paddy rice from India that was traced to Georgetown, Demerara. Rice, rye flour, beans, soy beans, eggplants, and gourd seeds have been found infested by it. The original generic and specific descriptions are reprinted, together with a translation of a description of the larva. A bibliography of 8 titles is appended.

Insects injurious to forests and forest products.—Damage to chestnut telephone and telegraph poles by wood-boring insects, T. E. Snyder (U. S. Dept. Agr., Bur. Ent. Bul. 91, pt. 1, pp. 11, pls. 2, figs. 3).—The author has found that serious damage is being done to the bases of standing chestnut telephone and telegraph poles in Maryland, Virginia, and other States.

In this paper particular attention is given to investigations made of the chestnut telephone pole borer, Parandra brunnea. Its injury to poles consists in large mines in the wood near the line of contact of the pole with the ground, necessitating the frequent resetting or even replacement of the damaged poles. The borers usually work in the outer layers of the wood at the base of the pole for a distance of from 2 to 3 ft. below, and sometimes from 1 to 2 ft. above the line of contact of the pole with the surface of the ground. The greatest damage is to that area just below and just above the surface of the ground, where the conditions of air and moisture are more favorable. Often, however, the entire butt up to a distance of 4 to 6 ft. and higher, according to the depth of setting, is mined. Poles that appear sound on the exterior may have the entire basal interior riddled and the work of the borers not be noticed until the poles break off. “It has also been determined that this beetle damages many species of living forest, fruit, and shade trees that have been previously injured by fire or other causes, and often leads to the destruction of trees that would otherwise recover from such wounds, and while not normally a primary enemy of trees, may thus become of more than secondary importance.”

The author concludes that the eggs are deposited from August to October in crevices on the exterior of the pole near the surface of the ground, the adults having been found flying from July to September. The pupal stage is passed in a broad chamber in the pole. The species is very widely distributed, ranging from Ontario, Canada, to Texas, eastward to the Atlantic coast, and westward to Arizona and southern California.

Inspections made near Dover, N. J., of a test line of poles set 8 years before and variously treated for preservation (brush treatments with a patented carbolineum preservative and spiritine, charring the butt, setting the pole in sand, and setting in small broken stone) and alternating with untreated poles, show
that although these methods may temporarily check the inroads of the wood-boring insects, they will not keep the insects out of the poles. In inspections made at Warren, Pa., and at Falconer, N. Y., of similar test lines treated by the creosote open tank method of impregnation and brush treatments of creosote, wood creosote, creolin, 2 different carbolineum preservatives, and tar, and which have been set in the ground for a period of 5 years, it was found that with the exception of the brush treatments with creolin and tar all were efficient in preventing the attacks of wood-boring insects.

"Methods of treating poles superficially by brushing with various preservatives have proved to be temporarily efficient in keeping wood-boring insects out, if the work is thoroughly done and not only the butt, but also the base, is treated. . . . It is evident that impregnating the poles with creosote by some standard process (either the open-tank or the cylinder pressure processes) will keep wood-boring insects out and preserve the poles for a much longer period than they would last untreated."

Brief notes are presented on the common injury to poles by associated wood-boring insects, including white ants (Formica rufa), the most common source of injury; a giant round-headed borer (Prionus sp.) sometimes found in poles, usually in association with the chestnut telephone pole borer; a large scarabaeid (Polyncha breviceps), previously found in decayed oak railroad ties, which causes the poles to break off sooner than they otherwise would; a flat-headed borer (Buprestis ruffipes); wireworms (Alaus sp.); a large black carpenter ant (Camponotus pennsylvanicus); and a small black ant (Crematogaster lineolata).

A list of some available publications on wood preservation is appended.

**Damage to telephone and telegraph poles by wood-boring insects, T. E. Snyder (U. S. Dept. Agr., Bur. Ent. Circ. 134, pp. 6, figs. 3).—**This circular consists of revised extracts from Bulletin 94, part 1, noted above.

**Studies in the life histories of Australian Odonata, R. J. Tillyard (Proc. Linn. Soc. N. S. Wales, 34 (1909), pt. 4, pp. 697-708, pl. 1, fig. 1).—**In this third paper (see E. S. R., 22, p. 356) notes are presented on the new species Phyllopetalia patricia.

**The African migratory locusts, W. La Baume (Tropenpflanzer, Beihete, 11 (1910), No. 2, pp. 65-128, pls. 4, figs. 10).—**Part 1 of this paper takes up briefly the general classification, geographical distribution, biology, natural enemies, and methods of combating locusts; part 2 is devoted to a more detailed account of six species.

**Notes on some new and rare Thysanoptera (Terebrantia), with a preliminary list of the known British species, R. S. Bagnall (Jour. Econ. Biol., 6 (1911), No. 1, pp. 1-11).—**This paper presents notes on 9 species representing 6 genera, of which 5 species and 1 genus (Amblythrips) are described as new. The list presented includes 74 species, representing 29 genera, known to occur in the British Isles.

**West African Hemiptera injurious to cocoa, G. C. Dudgeon (Bul. Ent. Research, 1 (1910), No. 3, p. 177).—**Sahlbergella singularis, a species nearly allied to the bark-sapper (S. theobroma), is reported to have been found badly infesting cocoa plantations in Bompata, Ashanti.

**On the presence in Dahomey and method of transmission of Leptomonas davidi, a flagellate parasite of the Euphorbiaceae, G. Bouet and E. Roubaud (Compl. Reud. Soc. Biol. [Paris], 70 (1911), No 2, pp. 55-57, figs. 12).—**The authors have found L. davidi in the latex of Euphorbia pilulifera in Dahomey but not in several other species examined. They do not think it to be pathogenic
as reported by Lafont (E. S. R., 24, p. 359). A lygeid bug, *Dieuches humilis*, was found to transmit the parasite from plant to plant.

On the transmission of *Leptomonas davidi* of euphorbias by a hemipteron, *Nysius euphorbiae*, A. Lafont (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 2, pp. 58, 59).—Experiments conducted show that a lygeid (*N. euphorbiae*) conveys the flagellate parasite *L. davidi* from diseased to healthy plants.

American Psyllidae, I, II (Triozinae), D. L. Crawford (*Pomona Jour. Ent.*, 2 (1910), Nos. 2, pp. 228-237, figs. 2; 4, pp. 317-362, figs. 3).—In the first paper the author presents a provisional key to the genera and species of the subfamily Triozinae, together with descriptions of 4 new species belonging to the genus Triozia. In the second paper 14 species and 1 variety of Triozia are described as new.

Three species of apple plant lice in Oregon, H. F. Wilson (*Oregon Sta. Cir., 12, pp. 3-8*).—A brief account is given of 3 species of plant lice that are causing serious damage to the apple in Oregon, namely, the green, brown, and woolly apple aphids. An account of remedial measures is included.

Aphididae of southern California, V, E. O. Essig (*Pomona Jour. Ent.*, 2 (1910), No. 4, pp. 335-338, figs. 2).—In this fifth paper (E. S. R., 24, p. 559) the author deals with *Aphis hederae* and *Nectaraphora pisi*.

A new mealy bug infesting walnut, apple, and pear trees, E. O. Essig (*Pomona Jour. Ent.*, 2 (1910), No. 4, pp. 339-345, figs. 2).—A mealy bug found to infest walnut, apple, and pear trees in Ventura County, Cal., is described as *Pseudococcus bakeri* n. sp. The species has not as yet become of economic importance.

The citrus mealy bug, E. O. Essig (*Pomona Jour. Ent.*, 2 (1910), No. 4, pp. 289-320, figs. 9).—This paper deals with the general history and distribution of *Pseudococcus citri* in California, its destructiveness, and quarantine measures, gives technical descriptions of the male and female, and discusses its life history, bionomics, natural enemies, and artificial control.

A synonymic bibliography is appended.

Some further observations on the scale insects (Coccidea) of the Uganda Protectorate, R. Newstead (Bul. Ent. Research, 1 (1910), No. 3, pp. 185-199, figs. 10).—Nine species and 1 variety, representing the genera *Inglisia*, *Lecanium*, *Ceroplastes*, *Dactylopius*, *Chionaspis*, and *Diaspis*, are described as new.

The alfalfa caterpillar (Eurymus eurytheme), V. L. Wildermuth (U. S. Dept. Agr., Bur. Ent. Cir., 133, pp. 11, figs. 8).—This circular is a partial report of work done by the author in the Imperial Valley, Cal., during 1910.

During the last 4 years the caterpillars of this butterfly have been reported as feeding on, and in some cases doing a large amount of damage to, growing alfalfa in the Southwest. In 1906 it was reported to be injuring lucern fields in Bighorn County, Wyo., and the following year damaging alfalfa at Hanford, Cal., and it is known to have injured alfalfa in Utah and Kansas. In Salt River and Yuma valleys, Ariz., and in the Sacramento Valley and in the irrigated alfalfa regions of south-central California, the pest is quite numerous during certain years and causes more or less damage. The injury during 1909 in the Imperial Valley, Cal., resulting in a loss of hundreds of dollars on a 320-acre ranch and similar losses on other ranches, led to the inauguration of the investigations here reported. In the West this insect is known to occur from Mexico northward into the Dominion of Canada, thus covering the chief alfalfa growing section of the United States.

Descriptions are given of the various stages in the life of this insect. There were found to be 4 distinct generations in the Imperial Valley in 1910, the last being less distinct than the others. The first generation covered the period
from March 15 to April 30; the second from May 1 to May 28; the third from May 28 to June 30; and the fourth from June 30 to July 15. Besides alfalfa the caterpillars are known to feed upon the 2 buffalo clovers, *Trifolium reflexum* and *T. stoloniferum*, which probably constitute its original native food plants, on white clover (*T. repens*), and in California on *T. tridensatum*, but does not appear to attack red clover. *Hosackia*, ground plum (*Astragalus corynocarpus*), and *A. crotalaria* have also been reported to be food plants of this insect. The butterfly is known to oviposit on *Medicago hispida*, and at Indio, Cal., on July 1 the author found larvae feeding on sweet clover (*Melilotus albus*), which they seemed to prefer to a patch of alfalfa growing close by.

Two tachinid parasites were bred by the author, namely, *Euphorocera claripes* from the larva, and *Masicca* sp. from the pupa. Several specimens of a chalcidid parasite (*Limnerium* sp.) were reared from the larvae and 1 specimen of *Calicis orata* from a pupa. The cotton bollworm, which is quite prevalent in the Imperial Valley and often mistaken for the alfalfa caterpillar, is said to be a ravenous enemy of the caterpillar, never eating alfalfa as long as it can find the larvae or pupae of *Euryamus*. A disease which destroys both the pupa and larva, but more often the larva, is prevalent all over the valley at all seasons of the year.

It is stated that control measures for this pest must be based upon methods of handling the crop. The author recommends that where caterpillars threaten the destruction of a crop of alfalfa before the hay can possibly mature, that it be mowed at once, cutting low and clean, especially along the ditch banks, borders, and turnovers. By so doing a large majority of that generation of caterpillars will be starved, thereby protecting the next crop as well as saving a part of the one already affected. Thorough and frequent irrigations should follow as soon as the crop of hay is removed from the ground.

A *California orange dog*, K. R. Coolidge (*Pomona Jour. Ent., 2* (1910), No. 4, pp. 333, 334).—The author has found *Papilio zelicaon* to be extremely abundant about Porterville and Lindsay in the San Joaquin Valley, Cal., the eggs being commonly deposited upon the lower surface of orange leaves. The species is widely distributed along the west coast from Mexico to Alaska and eastward to Montana and Colorado. Its normal food plants include various species of Umbelliferae, in the vicinity of San Francisco *Funicula vulgaris* and *Canum kelloggii* being most commonly fed upon.

It is thought quite probable that this insect will become of economic importance.

Scale-eating moths, W. W. Froggatt (*Agr. Gaz. N. S. Wales, 21* (1910), No. 9, p. 861).—Attention is called to the fact that all the Australian species belonging to the noctuid genus *Thalpocharis* are carnivorous in the caterpillar stage and feed almost exclusively upon the Coccidae. Caterpillars of *T. coccophaga* are known to be a great factor in their native state in devouring the white scale (*Eriococcus coriaceus*) upon young eucalypts and more recently have attacked the brown olive scale (*Lecanium olcae*), particularly upon citrus trees, in some districts almost freeing the trees of this pest. In addition to *T. pulvinaria*, which feeds upon *Pullinaria maskelli*, the author has bred another pearl-white species (*T. dubia*) from *Inquilina forminifer* and also from a *Lecanium* upon the cultivated fig. It is said that a fourth species, *T. pusilla*, has also been described from Australia with the same habits.

A *syntomid moth imported with bananas*, T. D. A. Cockerell (*Canad. Ent., 42* (1910), No. 2, pp. 60, 61).—A moth collected among bananas at Boulder, Colo., which is supposed to have been imported therewith from Central America, is described as *Ceramidina musicola* n. sp.
The wheat-head army worm (Meliana albilinea) as a timothy pest. R. L. Webster (Iowa Sta. Bul. 122, pp. 324–327, figs. 15).—During the summer of 1910 this insect became very abundant in northern Iowa and caused a large amount of damage, in some fields from 50 to 90 per cent of the timothy heads being injured. Their injury is caused by gnawing into the heads of timothy, wheat, rye, and other small grains, the timothy being preferred. The worms commence feeding at the bottom of the head and work upward, sometimes eating only one side or even less and sometimes taking practically all but the stem. Badly injured fields appear dry and brown in July and the denuded timothy heads are conspicuous even at some little distance.

The past history, destructiveness, distribution, food plants, classification, life history, and natural enemies of this pest are dealt with, together with a bibliography of 24 titles. The species appears to be a native of America, where it is found from Nova Scotia to Alberta in the North, to Delaware and New Jersey in the East, and at Glenwood Springs, Colo., and southern Arizona in the West. It has also been reported to occur in Mexico, Chile, and Argentina. In addition to timothy, it has been found to feed upon wheat, barley, rye, oats, sweet corn, sorghum, wild rice, Indian corn, and various grasses.

The author finds 2 distinct generations to occur in Iowa. Emerging in the spring from the pupal stage in which the winter is passed, eggs are deposited which commence to hatch toward the latter part of May. The young larvae begin to feed first on the tender green leaves of young timothy plants and later attack the heads. By the first of July some of the caterpillars are full grown, although they are not common until about the middle of that month. Mature larvae go into the soil to transform, the moths appearing again in August. The second generation of worms first appear in the field about the middle of August. The author’s observations indicate that in the spring the eggs are deposited on the crown of timothy plants only, whereas in August they are deposited in the sheath of the plant. From 3 to 10 days are required for their incubation, and about a month for the larva to complete its growth and enter the ground. In 16 cases 31 days was the average time spent as a pupa, the range being from 18 to 50 days. Technical descriptions of the egg, 7 larval instars, pupa, and adult are included.

Three tachniid parasites (Winthemia quadripustulata, Euphorocera claripennis, and Melachata helenus) were reared from the larva, the first-named being by far the most common. Three hymenopterous parasites (Microgaster auripes, Microplitis n. sp., and Paniscus geminatus) were also bred from the larva, the former being the most common. Penularphon retorridus was bred from the eggs and Apanteles lervicps is reported to have been reared from larva collected in New Mexico.

As preventive and remedial measures the author recommends keeping the wild grasses cut along the road sides and fence corners, early fall plowing which will bury the half grown caterpillars, and early fall pasturing (i. e., before the middle of September) to throw the second brood of caterpillars out of food.

A generic synopsis of the Itonidae, E. P. Felt (Jour. N. Y. Ent. Soc., 19 (1911), No. 1, pp. 31–62).—The author here presents the results of studies of the American species, many of the types of European genera, and the literature relating to the gall midges better known as the Cecidomyiidae.

Two new gall midges, E. P. Felt (Ent. News, 22 (1911), No. 3, pp. 109–111).—Two West Indian Cecidomyiidae, Asphondyliia vincini reared from the fruits of Jussica tinifolia and J. suffrutiosa, and Hyperdiplosis eupatori bred from a gall on the upper surface of the leaves of Eupatorium, are described as new.
Endaphis in the Americas, E. P. Felt (Ent. News, 22 (1911), No. 3, pp. 128, 129).—Two species of the European cercomyid genus Endaphis, namely, E. abdominalis, reared in Peru from cotton leaves badly infested with galls containing nites, and E. americana, reared from galls of Eriophyes fraxiniiflora on Fraxinus rotundifolia at Prescott, Ariz., are described as new.

Dengue and Stegomyia, J. Legendre (Bul. Soc. Path. Exot., 4 (1911), No. 1, pp. 26–36).—During the course of an epidemic of dengue fever which prevailed for many months at Hanoi, French Indo-China, during which the major part of the population, both native and European, suffered, the author made numerous observations and was led to conclude that the Stegomyia mosquito was the active agent in its transmission.

Mosquitoes and malaria, H. Waite (Biometrika, 7 (1910), No. 4, pp. 421–436, dgm. 5).—A study of the relation between the number of mosquitoes in a locality and the malaria rate.

Myiasis dermatosa due to the ox warble flies, R. T. Miller (Jour. Amer. Med. Assoc., 55 (1910), No. 23, pp. 1978, 1979).—The author reports a case in which the larva of Hypoderma lineata in the second stage was taken from the knee of a human patient from Roanoke, Va.

The Mexican orange maggot (Anastrepha [Trypetia] ludens), D. L. Crawford (Pomona Jour. Ent., 2 (1910), No. 4, pp. 321–332, figs. 4).—The author reports having found this pest in 1910 at several points in the State of Chiapas, Mexico, and that it is also present in the fruit districts of Cordova, Oaxaca, Jalapa, and Colima. A parasite taken by him in the act of depositing eggs in the maggots in oranges, mangoes, and guavas has been identified as Diachasma sp.

The author considers the great and immediate danger from the maggot to be to the citrus groves of Texas, New Mexico, and Arizona.

On the raising of sterile flies, E. Wollman (Ann. Inst. Pasteur, 24 (1911), No. 1, pp. 79–88, figs. 2).—A contribution to the knowledge of the rôle of microbes in digestive tracts. Calliphora vomitoria and Lucilia casar were used in the studies here reported.

On the biology and pæcilogonic viviparity of the cattle fly (Musca corvina) in tropical Africa, E. Roubaud (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 3, pp. 158–160).—Observations made in Dahomey are here reported.

Studies of the stomoxyses of Dahomey, B. Roubaud (Bul. Soc. Path. Exot., 4 (1911), No. 2, pp. 122–132).—The stomoxyses are represented in Dahomey by 2 genera, Stomoxys and Lyperosia. Systematic and biological notes are presented on 8 species of Stomoxys that occur in the colony. A single and little-known species, longipalpis, is the only representative of the genus Lyperosia.

In September the author received from Abomey a collection of dead flies (S. calcitrans) that were affixed in large numbers to potato leaves and also reported by the sender to be found upon the bodies of asses. Examination showed that they had been destroyed by an entomophthorous fungus. In experiments conducted it was discovered that through the ingestion of spores, the house fly could also be infected. The complete development of the mycelium that causes the death of the fly takes place in 24 hours, and the maximum period required by the fungus to kill the fly does not exceed 4 days.

On West African Trypetidae (fruit flies), W. M. Graham (Bul. Ent. Research, 1 (1910), No. 3, pp. 161–171, pls. 3, fig. 1).—Two species of fruit flies of the genus Ceratitis and 3 of the genus Dacus are described as new.
A new dipterous parasite of bats, T. D. A. Cockerell (Canad. Ent., 42 (1910), No. 2, pp. 59, 60).—The hippoboscid here described as Triechobius cornuhosti n. sp. was taken from a bat (Corynorhinus macrois pallescens), collected in Boulder County, Colo.

Rat fleas in German East Africa, A. Schuberg and P. Manteuffel (Arb. K. Gesellschaft, 33 (1910), No. 3, pp. 559-561; abs. in Bull. Inst. Pasteur, 8 (1910), No. 10, p. 476).—Of 258 fleas taken from Mus rutilus, M. decumanus, and M. alexandrius at Daresalam, 172 or 66.6 per cent were Lomopsylla cheopis, 28 or 10.9 per cent were L. scapulifer, and 58 or 22.5 per cent were Sarcoptes stylosthes.

The plague in North China, J. J. Mullahney (Jour. Amer. Med. Assoc., 56 (1911), No. 10, p. 737).—It is stated that the rat and the rat flea apparently do not have as much to do with the spread of pneumonic plague as is the case in epidemics of the bubonic type. "It has been conclusively shown that the disease, in the pneumonic form, is transmitted by the spumum and by contact with persons sick of the disease, and that the wearing of respirators is good prophylaxis."

Papers on cereal and forage insects.—The timothy stem-borer (Mordellistena ustulata), a new timothy insect, W. J. Phillips (U. S. Dept. Agr., Bul. Ent. Bull. 95, pl. 1, pp. 9, pl. 1, figs. ½).—This new timothy insect has been found in Kentucky, Tennessee, Ohio, Indiana, Illinois, and Missouri, boring in the stems of timothy and in many cases traversing the entire length from the top joint to the bulb. Thus far, however, it has not proved a serious pest, having been found only in small numbers at any given point. It occurs in the Middle and Southern States, the adults having been captured as far east as Pennsylvania and been bred from material collected in Virginia.

As a rule the eggs are deposited at or slightly below the center of the first or second joint in timothy, but much farther down the stem in other grasses. From here the larva bores into the center of the stem and then begins its downward journey to the bulb or root. "This species has been reared from timothy, orchard grass (Dactylis glomerata), quack grass (Agropyron sp.) and Agrostis alba, while larvae that were supposedly this species have been found in bluegrass (Poa spp.) and cheat (Bromus scabellus)."

Detailed technical descriptions are given of the egg, larva, and pupa. "The larval stage covers a period of about 11 months. Nothing could be learned about the number of molts, as the larvae will not develop if their galleries are disturbed. The pupal stage varies from 11 to 16 days, depending, apparently, upon the temperature. The adult beetles will live from 5 to 6 days in confinement, but they will probably survive a much longer period in the open. The insect hibernates in the larval stage. About the time freezing begins in the fall the larvae are down to the bulb or crown of the root, where they are well protected from cold."

Three species of parasites have been bred from the larva, namely, Hetcospilites mordellistenea in Ohio and Indiana. Schizoprymnus phillipsi in Indiana, and Merisnus mordellistenea in Ohio and Indiana. It is thought probable that the parasitic enemies keep the beetles in check. In case of a serious outbreak it is recommended that a short crop rotation be adopted, allowing a field to remain in timothy sod not more than 2 or 3 years, and thus preventing the stem-borer from becoming well established. Borders of the fields and waste places should be mowed frequently during the months of June and July.

An insect pest in belladonna, P. E. F. Perredes (Brit. and Colon. Druggist, 58 (1910), No. 5, pp. 107-109, figs. 3; Pharm. Jour. [London], 4, ser., 31 (1910), No. 2441, pp. 135-137, figs. 3).—A flea beetle (Epitrix atropa) is reported
to be the source of considerable damage to belladonna plants in the vicinity of Hitchin, Hertfordshire, especially during dry seasons.

The cherry stem borer, Semasia woeberiana, W. E. Collinge, (Jour. Bd. Agr. [London], 17 (1911), No. 10, pp. 828-839).—This insect was the source of injury to cherry trees in various parts of Kent and Hertfordshire in 1908 and increased in abundance during 1909 and 1910.

A new cotton pest, Aulmann (Tropenlandw., Beilage Kolon. Ztschr., 1 (1911), Nos. 1, pp. 3, 4; 3, pp. 9-11, figs. 9).—The curculionid beetle Alcides brevirostris is reported to injure cotton in German East Africa by girdling the stalks.

Steirastoma depressum, "cocoa-borer beetle," J. L. Guppy (Bul. Dept. Agr. Trinidad, 9 (1910), No. 66, pp. 186-191).—An account is given of the life history, distribution, and control of the cocoa-borer beetle which has been a serious pest and source of annoyance to planters in several parts of Trinidad. It is also said to be found in Venezuela, Colombia, Surinam, British Guiana, Grenada, and Guadeloupe.

Notes on Lixus marginatus, M. A. Yothers (Canad. Ent., 42 (1910), No. 3, pp. 69-71, pl. 1).—L. marginatus is reported to have been bred from swellings, about the size of peas, on the stems of Polygonum litorale growing at East Lansing, Mich.

Revision of the Australian Curculionidae belonging to the subfamily Cryptorrhynchidae, A. M. Lea (Proc. Linnean Soc. N. S. Wales, 31 (1909), pl. 4, pp. 593-635).—A continuation of the work previously noted (E. S. R., 22, p. 363).

Studies of the honeybee (Apis mellifica), E. Zander (Ztschr. Wiss. Zool., 95 (1910), No. 4, pp. 507-550, pls. 3, figs. 14).—The author publishes the first two of a series of studies of the honeybee. The first paper contains a full description of the development and comparative anatomy of the thoracic exoskeleton of bees and wasps with special reference to the disputed point of the exact composition of the thorax. In the second paper the structure and mechanism of the flight apparatus of the honeybee are discussed by F. Steilwaag.

A new pteromalid parasitic on Tortrix fumiferana, C. T. Brues (Canad. Ent., 42 (1910), No. 8, pp. 259, 260).—Nasonia tortricis, the species here described as new, was bred from pupae of the spruce budworm (T. fumiferana), collected at Baskatong, Quebec.

Descriptions of 3 new North American species of the mymarid genus Polynema, parasitic on membracid eggs, with a list of the species described since the year, 1898, A. A. Girault (Jour. N. Y. Ent. Soc., 19 (1911), No. 1, pp. 12-23).—The parasites here described are P. striaticorne, parasitic on the egg of Ceresa lubatus and C. taumina in New York, Missouri, and Illinois; P. euchennopa, bred from the eggs of the membracid Euchennopa binotata in Illinois; and P. citripes, a manuscript name given by Ashmead.

Some remarks on the parasites of the large larch sawfly, Nematus erichsonii, J. Mangan (Jour. Econ. Biol., 5 (1910), No. 3, pp. 92-94).—In the Lake district in 1908 about 6 per cent of the cocoons of this sawfly were parasitized by Mesoleius aulicus. In 1909 the proportion had increased to 15 per cent, while in 1910, some 62 per cent were parasitized. The ovaries from individual parasites kept in captivity usually contained about 30 eggs, although in some cases as many as 40 mature eggs were found. In 1909 about 0.3 per cent of the cocoons furnished specimens of the ichneumon Microcryptus labralis. A tachinid, Exorista dubia, was also bred from the cocoons. The parthenogenetic
origin of the majority of the sawfly larvae is stated to have been evident, as hardly more than 0.2 per cent of the sawflies emerged were males.

The larch sawfly (Lygeureinematus erichsonii) in Minnesota, A. G. Ruggles (Canad. Ent., 42 (1910), No. 3, pp. 93, 94)._Brief notes are presented upon the occurrence of the larch sawfly which has become a very serious pest of tamaracks in northern Minnesota.

Some new and unrecorded endoparasites from Australian chickens, Georgina Sweet (Proc. Roy. Soc. Victoria, n. ser., 23 (1910), No. 1, pp. 242-256, pls. 5)._The species recorded from chickens are Chaoanotamia infundibulum which is fairly common in the suburbs of Melbourne, Dacinaea cesticillus, D. tetragona, D. variana n. sp., Heterakis perspicillum which was found in the small intestine of 25 per cent of the fowls examined from Victoria, H. papillosa which appears to be common in fowls around Melbourne, H. maculosa, Trichosoma rectum, and Oxyspirura paporum n. sp. which causes "worm in the eye" in Queensland poultry. The last-mentioned species is extra-ocular, like O. mansoni, occurring in numbers beneath the nictitating membrane; at Cairns, North Queensland, it is very common, often being the source of serious loss.

A list of the metazoan parasites recorded to date from Gallus domesticus in Australia is appended.

The distribution of the Rocky Mountain spotted-fever tick, F. C. Bishop (U. S. Dept. Agr., Bull. Ent. Circ. 136, pp. 4, fig. 1)._The account here presented of the distribution of Dermacentor venustus is based on 815 lots obtained from 225 different localities in 10 States, the representation being as follows: California 3, Colorado 15, Idaho 42, Montana 72, Nevada 11, New Mexico 2, Oregon 15, Utah 12, Washington 27, and Wyoming 26.

"The northern part of the Rocky Mountain region in the United States is the territory principally infested, but the river valleys and sagebrush plains to the west are more or less heavily infested. Although the spotted-fever tick occurs in the eastern edge of the Cascade Mountains, it does not appear to exist in the main Cascade range, and has never been found to the west of the divide formed by those mountains. It has been found in the western portion of the Black Hills of South Dakota, and probably occurs throughout those hills. There is no doubt that the species is common in southern British Columbia and possibly eastern Alberta. Two females were collected...at Kaslo, British Columbia...

This tick does not seem to be limited particularly as regards life zones. It appears to be most abundant in the Transition Zone, but occurs commonly in the Canadian and Upper Sonoran Zones. It is probably also to be found in the Hudsonian Zone. Specimens have been collected at various elevations from slightly over 500 ft. to nearly 9,000 ft. above sea level. The species seems to reach its highest development and occur in greatest numbers between 3,000 and 5,000 ft."

Attention is called to the fact that the abundance of this tick is greatly influenced by the presence of numerous host animals as well as by the protection afforded by timber. The immature ticks were found to feed almost exclusively on small mammals and adults on the large domestic animals. Mention is made of the fact that the distribution of the ground squirrel subgenus Colobotis corresponds very closely to the area in which the spotted-fever tick occurs.

Bird enemies of the Texas-fever tick and other ticks, W. L. McAtee (Auk. 28 (1911), No. 1, pp. 136-138)._The recent literature relating to the subject is reviewed. It is stated that "in the course of stomach examinations by the Biological Survey, the following birds have been found to eat ticks: Those eating Texas-fever ticks are killdeer (Oxyechus vociferus), upland plover (Bartramia
longicunda), and meadowlark (Sturnella magna); net ticks (Dermacentor occidentalis), dwarf hermit thrush (Hylocichla guttata nana); castor-bean ticks (Ixodes sp.), boat-tailed grackle (Quiscalus major), meadowlark, and house wren (Troglodytes aëdon); and Gamasus sp., the wren tit (Chamaea fasciata)."

New predaceous and parasitic Acarina, H. E. Ewing (Psyche, 18 (1911), No. 1, pp. 37–43, pl. 1).—Several of the 8 species here described are of economic importance, particularly Tydeus coccophagus, which was found in large numbers attacking the oyster-shell scale during August, and Tarsonemus chionaspivorus, taken from Chionaspis sp. on poplar, both at Ames, Iowa.

A common sumach gall produced by a mite, T. D. A. Cockerell (Science, n. ser., 32 (1910), No. 831, pp. 796, 797).—A mite which produces gall masses on Rhus glabra cismonitana in Colorado is described as Eriophyes rhoinus n. sp.

An introduction to the physiology of the Protozoa, S. von Prowazek (Einführung in die Physiologie der Einzellige (Protozoen). Leipzig and Berlin, 1910, pp. 61–172, figs. 51).—A comprehensive work on the physiology of the Protozoa.

A monograph of the tapeworms of the subfamily Avitellinina, being a revision of the genus Stilesia, and an account of the histology of Avitellina centripunctata, L. H. Gough (Quart. Jour. Micros. Sci. [London], n. ser., 56 (1911), No. 222, pp. 317–385, pls. 8, figs. 6).—In this monograph 4 species of Stilesia are recognized, namely, globipunctata, vittata, hepatica, and sjöstedti. The genus Avitellina is erected for S. centripunctata, which occurs in the small intestine of sheep in Italy, Algeria, and South Africa.

Tapeworms of South American Felisca, M. Lhie (Zool. Jahrbr., 1910, Sup. 12, No. 3, pp. 637–710, pls. 2, figs. 8; abs. in Jour. Roy. Micros. Soc. [London], 1911, No. 1, p. 49).—The author finds that Tanina oligarthra from Felis concolor is nearly allied to T. echinococcus, and that Cysticercus macroystis from Lepus brazilius is the bladder-worm stage of a new tapeworm, T. macroystis, from species of Felis. T. omissa from F. concolor and from other species of Felis is described as new.

FOODS—HUMAN NUTRITION.

A bacteriological study of ham souring, C. N. McBryde (U. S. Dept. Agr., Bur. Anim. Indus. Bull. 132, pp. 55, pls. 4, figs. 5).—From an extended investigation the author concludes that ham souring as encountered in the wet curing process, where hams are entirely submerged in pickling fluids, is due to the growth within the ham of an anaerobic bacillus (Bacillus putrefaciens n. sp.).

This micro-organism was isolated and studied and its characteristics described. As the author points out, it belongs to the class of putrefactive anaerobes which are widely distributed in nature in dust, soil, and excrementitious matters, and as it or its spores may be present in the dust and dirt of packing houses, the hams may become contaminated in the various manipulations to which they are subjected.

"A preliminary study of the chemical changes which take place in the process of souring shows that these changes are of a putrefactive nature, and ham souring, as ordinarily encountered, is to be regarded as an incipient putrefaction. Hams which had been artificially soured by the injections of culture were compared with sour hams obtained from the packing house, and the putrefactive changes were found to be identical.

"Hams which have once become sour can never be restored to a sound condition, because of the chemical changes which result from the growth of the bacillus. . . .
"The salts of the pickling fluids have a marked inhibitory action on the ham-souring bacillus, and sours occur less frequently in regular-cure hams. In regular-cure hams the growth of the ham-souring bacillus is restricted and often completely inhibited as a result of the additional pumping which these hams receive, whereby they are more or less saturated with pickle at the beginning of the cure. . . .

"Under the present methods of curing, the partly pumped or mild-cure hams furnish the greater proportion of the sours, as these hams are not pumped in the body and the growth of the ham-souring bacillus within the bodies of these hams is not interfered with until the curing pickle has penetrated from the outside. . . . The percentage of souring in the mild-cure hams could be greatly reduced without materially affecting the cure by pumping these hams with their own curing pickle. . . .

"The only way by which ham souring could be entirely eliminated from the larger packing establishments under the present methods of curing would be to handle the hams throughout under aseptic conditions, and this, for obvious reasons, would be an impossibility. The losses from ham souring may be materially reduced, however, by greater care in handling the hams and the adoption of precautionary measures designed to prevent the introduction of contaminated foreign matter into the bodies of the hams, together with more thorough methods of pumping.

Additional experiments on the glucose of eggs and its biological significance, V. DiLamare (Seperat from Rend. Accad. Sci. Fis. e Mat. Napoli, 3. ser., 16 (1910), No. 7-9, pp. 242-244; abs. in Chem. Zentbl., 1910, II, No. 24, p. 1763).—The author studied the occurrence of sugar in hen's eggs and turtle eggs. In eggs almost fully developed, dialyzable sugar was found in a quantity as great as or greater than that of the hydrolyzable sugar. In eggs not fully developed the latter was more abundant, while in very small eggs no glucose was identified.

The use of refrigeration in bread making, E. Brandeis (1. Cong. Internat. Froid, [Paris], Rap. et Commun., 1908, III, pp. 98-112).—On the basis of experimental data the importance of artificial refrigeration in modern bakeries is discussed. According to the author, low temperature hinders the deterioration of stored materials, lessens the danger from explosions, favors the change of gluten into soluble material by the agency of the enzyme present in the flour, lessens the acid content of bread, acts favorably upon the bread-making quality of the flour, and is beneficial in other ways.

Experiments regarding sterilizing flour with reference to panary fermentation, A. J. J. Vandevenche (Acad. Roy. Belg., Bull. Cl. Sci., 1910, No. 7, pp. 597-610).—In connection with a study of the function of different organisms concerned in panary fermentation some experiments are reported in which flour was sterilized with a mixture of chloroform and acetone and with formalin.

The chloroform-acetone mixture seemed to destroy all the organisms present in the flour with the exception of Bacillus mesentericus vulgaris, but it also modified the properties of the gluten. Formalin proved to be either insufficient as a sterilizing agent or enough remained in the flour to prevent its subsequent use as a culture medium. The conclusion was therefore reached that satisfactory means have not as yet been found for sterilizing flour, and the author proposes to continue his observations.

Flour used to prevent bread from sticking to the oven, K. Mois and C. Güttler (Ztschr. Gesam. Getreidez., 3 (1911), No. 1, pp. 7-12).—The composition, physical properties, and usefulness were studied of several sorts of materials, such as are used to sprinkle on the floors of bakers' ovens to prevent bread from sticking or burning. The materials consisted of finely ground wood, oat hulls, rice hulls, leaves, and similar substances. The authors point out that these goods must be kept dry as they readily become moldy.

"Narras," an important native foodstuff in German Southwest Africa, C. Grimme (Tropenpflanzer, 14 (1910), No. 6, pp. 297-302; abs. in Chem. Zentrhl, 1911, I, No. 1, pp. 32, 33; Umschau, 15 (1911), No. 11, pp. 224-226, figs. 2).—Analyses are given of preparations made from the fruit and seed of a cucurbit (Acanthosicyus horridus). A light yellow oil of mild flavor, it is stated, is prepared from the seed.

Principles in jelly making, Nellie F. Goldswaite (Univ. Ill. Bul., 8 (1911), No. 7, pp. 19, pl. 1).—Jelly making with a variety of fruits is discussed on the basis of experiments previously reported (E. S. R., 24, p. 363).

Some of the author's conclusions follow:

"Fruit juice to be used for jelly making must contain pectin. It must also be acidic. Juices, which are to be used for jelly making, should be cooked out of the fruit. The most common cause of failure in jelly making is an over-proportion of sugar to juice, i.e., to the pectin in the juice. A short, quick test in jelly making is preferable to a test which involves a waste of time.

"There need be no 'second' quality of jelly. All may be of first quality if the juice is properly extracted and handled.

"Experiments, so far, indicate that the mean boiling process in jelly making is preferable to the long boiling, or to the short boiling process. Any given juice, when once the boiling is begun, should be transformed into jelly as rapidly as possible. The time necessary for the boiling of a quantity of jelly apparently varies with several factors: The proportion of sugar to juice, the proportion of pectin in the juice, and possibly too with the acidity of the juice. The hot jellies should be poured at once into hot sterilized glasses, and after having 'set,' should be carefully sealed.

"Jellies from but slightly acid fruits may be made by adding a vegetable acid to the juice, but this process is not recommended except in the case of sweet apple or quince juices. Cherry and strawberry jellies are possibilities if the hot mass is boiled somewhat beyond the first jelly test observed. The white inner skins of oranges and of lemons are prolific sources of pectin. Hence genuine jellies from these fruits may be made. The pectin from these skins may also be used for strengthening other fruit juices.... Blueberries are recommended as an excellent fruit for jelly making.

"Beet sugar and cane sugar may be used interchangeably in jelly making."

Table jellies, W. W. O. Beveridge (Jour. Roy. Army Med. Corps, 16 (1911), No. 1, pp. 1-8).—The observations and experimental data reported have to do particularly with gelatin goods such as bottled jellies, cakes or tablets, and granulated powder for jelly making, calf's foot jelly, and meat jellies.

With respect to the prevalent idea that jelly made from calves' feet is superior to that obtained from other sources, the author points out that such jelly contains "nearly always some native protein, that is, albumin and globulin." He believes that tryptophane is frequently present, as well as traces of phenol compounds, and in support of this opinion reports some data regarding the
examination of calf's foot jelly in comparison with jelly obtained from granulated jelly powder and pure gelatin.

Samples of granulated jelly powders were found to contain on an average from 13 to 17 per cent gelatin, about 80 per cent sugar, from 1.5 to 2.5 per cent tartaric or citric acid, and certain flavoring and coloring matters.

To insure transparency in such jellies the water added should be below 90° C. In temperature. The jellies may be strained through muslin if necessary.

Various questions concerned with jelly and jelly making are discussed, particularly meat jellies.

Quotations from the author's discussion follow:

"A table jelly [made with gelatin, such as is often used for dessert] consists of water, gelatin, sugar, fruit essence, and a vegetable acid. As the essential part of a jelly other than sugar is gelatin it will only be necessary to consider this from a chemical and physiological point of view. . . .

"By continuous boiling with water gelatin is converted into a nongelatinizing form called β-gluten, and this reaction may partly account for the fact that some jellies will not set under any ordinary conditions. In the same way repeated heating and cooling destroys the property of gelatinizing, and the power to form a jelly is entirely lost by heating under increased pressure to 140° C.

"Aqueous solutions of the salts of monobasic acids, except alkali formates and acetates, retard the coagulation of gelatin, while salts of the dibasic and tribasic acids, polyhydric alcohols, and sugars increase the rate of coagulation. Crystalloids which increase the viscosity of water increase the viscosity of colloidal solutions.

"Gelatin has one great advantage—that it is easily digested in the stomach, and also has the power of fixing excess of acidity; thus it can well be prescribed in certain disorders of the gastric digestion. In the first stage of digestion it loses its property of gelatinizing, and is formed into gelatin proteoses, gelatose, and gelatin peptones.

"What little nutritive value table jellies contain is dependent more upon the sugar, amounting to from 50 to 80 per cent, than upon the small amount of gelatin present. The gelatin usually amounts in most table jellies to from 13 to 17 per cent, hence as protein spacers in certain ailments their usefulness is somewhat restricted, and there is no reason to suppose that gelatin is converted into protein within the body. As a source of heat and energy it has decided value, for 1 gm. yields nearly as much of these as 1 gm. of protein or carbohydrate—namely, 4.1 calories. Ordinary gelatin produces 1,570 calories per pound."

The author describes the method which he follows in the examination of materials containing gelatin.

Lacto—a new and healthful frozen dairy product, M. Mortensen and J. Gordon (Iowa Sta. Bul. 118, pp. 268–279, charts 2).—The authors have obtained favorable results in a study of the preparation of a frozen product of the same consistency as ice cream, made from fermented milk, to which eggs, sugar, and flavoring material have been added.

It is stated that even when buttermilk of good quality has been used it has not been possible to produce a combination of flavors which was entirely palatable. On the other hand, when milk soured with a commercial lactic-acid culture was used the product, for which the name "lacto" is proposed, was found to be satisfactory.

Directions are given for souring the milk which, when ready for use, has an acid content of from 0.7 to 0.8 per cent expressed in terms of lactic acid. The milk must be "of a mild and clean acid flavor. The curd must be thoroughly
broken up. This is accomplished by pouring it from one pail to another until it is as smooth and velvety as rich cream."

Studies of the bacterial content of "lacto" showed that the lactic-acid bacteria remain alive for some time after the product is frozen but that there is no further bacterial growth or production of acid. The number of lactic-acid bacteria decreases gradually after freezing and the decrease grows more pronounced toward the end of the storage period. As regards the effects of the flavoring materials used, it was found that orange and pineapple flavoring appeared to reduce the number of bacteria, their action being probably only indirect, ascribable to the fact that such materials increased the acidity of the sour-milk mixture.

Formulas are given for making "lacto" of different sorts, the suggested flavoring material in most cases being fruit juices.

The authors discuss the possible favorable action of the lactic-acid bacteria in diminishing intestinal putrefaction.

Extended tests showed that "lacto" was generally relished.

The use of homogenized butter and skim milk in the manufacture of ice cream (U. S. Dept. Agr., Food Insp. Decision 132, p. 1).—The Board of Food and Drug Inspection is of the opinion that mixtures of skim milk and butter fat, when homogenized, are not entitled to the name of "milk" or "cream" and that the product made from a homogenized butter or skim milk can not be properly called "ice cream."

Cocoa and chocolate—a short history of their production and use (Dorchester, Mass., 1910, pp. 69, pls. 5, figs. 60).—Historical, botanical, and descriptive material is presented as well as a description of the various processes followed in preparing chocolate and cocoa for the market. A brief paper entitled Suggestions Relative to the Cooking of Chocolate and Cocoa, by Ellen H. Richards, is also included.

Tomato catsup and food inspection, R. O. Brooks (Spice Mill, 34 (1911), No. 3, pp. 202, 203).—A critical discussion of data reported by the Connecticut State Station (E. S. R., 24, p. 505), with suggested standard limits for catsup made from whole tomato pulp only.

Food inspection decision (U. S. Dept. Agr., Food Insp. Decision 133, p. 1).—This decision has to do with the coloring of green citrus fruits by holding them in a warm, moist atmosphere for a short period of time after removing from the tree.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 768-769, pp. 2 each; 770-772, p. 1 each; 773-774, pp. 2 each; 775, p. 1; 776-777, pp. 2 each; 778, p. 1; 779, pp. 2; 780, p. 1; 781-785, pp. 2 each; 789, p. 1; 790-792, pp. 2 each; 793, p. 1; 795-797, pp. 2 each; 799, pp. 3; 800, pp. 1; 801, p. 1; 802-805, pp. 2 each).—These notices of judgment have to do with the adulteration of tomato catsup, frozen eggs, shucked oysters, a food product (Maclaren's imperial cheese), flour, tomato pulp, tomato paste, and spiced catsup; the misbranding of drug products, Geneva gin, coffee, vanilla flavor and lemon flavor, macaroni, salt fish, olive oil, and table sirup; and the adulteration and misbranding of a lemon-extract compound, peppermint extract, "Prime Italian Codfish," drug products, "Red Seal Cola Queen Sirup," apple phosphate, and maple sirup.

Enforcement of the food and drugs act for the years 1908 and 1909, R. M. Allen (Kentucky Sta. Food and Drugs Rpt. 1908–9, pp. 29).—The work carried on in the State under the food and drugs act is described, and prevailing conditions and other food topics discussed. It is stated that during the period covered by the report 3,410 samples of food and drugs, taken from markets throughout the State, have been analyzed, of which 1,004 were found to be adulterated
and misbranded, together with 740 miscellaneous and unofficial samples, taken for study or submitted by consumers. The work of inspection of the sanitary condition of factories, grocery stores, bakeries, etc., has been extended.

Food and drug inspection (Ann. Rpt. Bd. Health Mass., 41 (1909), pp. 425-440).—This is a summary of data concerning the activities of the department along this line during the year ended November 30, 1909. The total number of examinations of food and drugs was 7,337. Of these 5,796 were found to be of good quality.

First annual report of the department of food and drugs inspection for the year ending December 31, 1910, S. C. Dinsmore (Nevada Sta. Bul. 74, pp. 68).—Data are reported of the examination under the state pure food law of a large number of samples of dairy products, milk, ice cream, ice cream cones, vinegar, flavoring extracts, jams, jellies, beverages, and miscellaneous food materials.

Various food inspection decisions are quoted, Circulars 2-11 reprinted, and pure food topics discussed.

Experiments on artificial refrigeration in Danish agricultural technology, N. Steenberg et al. (I. Cong. Internat. Froid, [Paris], Rep. et Commun., 1908, III, pp. 576-589, dgsms. 4).—The experiments reported have to do with refrigeration in connection with the storage and shipment of agricultural products, particularly butter and meat.

The value of refrigeration in the food supply of the poorer classes, P. B. Proctor (I. Cong. Internat. Froid, [Paris], Rep. et Commun., 1908, III, pp. 927-931).—The effect of refrigerated produce on market values and similar questions are considered.

[Food, diet, and agriculture in Tibet], S. Hedin (In Trans-Himalaya—Discoveries and Adventures in Tibet. New York, 1909, vols. 1, pp. XXIII + 436, pls. 117; 2, pp. XVII + 439, pls. 95, maps 3).—The author records much information regarding the food habits and customs and the food supply of the Tibetan nomads and dwellers in towns and in the monasteries, and also gives data regarding the agriculture and agricultural resources of the country.

Flocks and herds of sheep, yaks, goats, and horses represent the chief wealth of the Tibetan nomads, while in localities where agriculture is possible many of the inhabitants cultivate the soil, barley and other grains, peas, vegetables, and fruits being grown. Milk, meat, rice, parched barley, and tea stirred up with butter are staple foods of the people as a whole.

Digestion and nutrition, G. H. Roger (Digestion et Nutrition. Paris, 1910, pp. XIV + 624).—In this extended handbook such subjects are considered as the general properties of fermentations; ferment action; distribution and preparation of ferments; proferments, fermentations, coferments, and antifermets; digestion of carbohydrates; glycosuria; metabolism of fat (obesity); proteid digestion; proteid putrefaction; and body secretions and their role in nutrition. As a whole the volume constitutes a digest of data regarding digestion and its relation to general nutrition.

decrease in the power to assimilate glucose after the onset of atrophy of the pancreas. The persistence of a low limit of assimilation for more than a year, which was noted in the data reported, shows, according to the authors, that the other organs of the body compensated imperfectly, if at all, for the pancreatic insufficiency. The limit of assimilation in a dog with atrophy of the pancreas, which had been under observation 14 months, was increased more than 100 per cent by feeding fresh pancreas. The data are also considered from the standpoint of diabetes.

The paper is followed by a discussion.

The influence of water on gastric secretion and the chemical affinity of mucus for hydrochloric acid in the stomach. N. B. Foster and A. V. S. Lambert (Proc. Soc. Exp. Biol. and Med., 4 (1906), No. 1, p. 13).—Dogs with Pawlow fistulas were used as subjects in the authors' experiments, which are briefly summarized:

"It was observed that with definite amounts of cracker meal as food, the amount and rate of gastric secretion depend to some extent on the amount of water given the dog with his meal, i. e., when small amounts of water are given, the secretion is slow and scanty. If larger quantities of water are mixed in the food the secretion is more abundant.

"The degree of acidity of gastric juice depends upon the amount of secretion. When this is considerable it is much more acid than when the secretion is scanty. Pawlow is of the opinion that the degree of acidity of the gastric juice is constant; this can hardly be correct, however, for the total acidity changes from hour to hour. The proportion of free acid depends upon the amount of mucus secreted, since mucus protein like other proteins combines with HCl. Mucus in the presence of pepsin combines with HCl to a considerable extent and undergoes digestion, with formation of proteoses."

Concerning the ash content of an unrestricted diet, R. Tigerstedt (Skand. Arch. Physiol., 24 (1910), No. 2–4, pp. 97-112).—The author reports determinations of the ash content of the food materials in the dietaries of Finns reported by Sundström (E. S. R., 24, p. 171).

According to his summary, the amount of phosphorus assumed to suffice for equilibrium is from 2.0 to 3.5 gm. per day. The average amount found in the diet of the men included in the study was 4.33 and in the diet of the women 2.77 gm. In the case of individuals with average muscular work, the diet supplied on an average 3.57 gm. per day. In the case of calcium, the diet of the men supplied 3.70 and that of the women 2.29 gm., or 2.87 gm. for a moderate work ration having an energy value of from 3,000 to 3,500 calories. The assumed average amount of calcium required per day, it is pointed out, is not greater than 1 gm. The amount of magnesium considered necessary for equilibrium is not far from 0.5 gm. per day. In the dietary studies, the diet of the men supplied 1.00 and that of the women 0.66 gm., with an average of 0.92 gm. for the diet for a man at moderate work.

According to the author, it should be assumed that, as is the case with nitrogen, equilibrium can be obtained with different quantities of ash constituents, and the amount required for maintaining equilibrium is not constant but probably varies within wide limits. That this is the case is indicated by the variations observed in individual cases. The difference between the total ash of the diet and the sum of the amounts of phosphoric acid, calcium oxide, and magnesium oxide may be assumed to consist chiefly of sodium chlorid. If this is the case, the dietary of the men studied would supply on an average 42 gm. per day and that of the women 28 gm. The ratio of the mineral constituents to each other and similar questions are discussed. It is pointed out by the author that the fairly large amount of phosphorus, calcium, and magnesium
in these diets in comparison with American diets is probably due to the large amounts of milk which were consumed.

Sodium chloride and potassium salts, E. Biernacki (Ztschr. Expt. Path. u. Ther., 8 (1911), No. 3, pp. 685-694).—The author reports and discusses experiments which have to do with his theory regarding the relation between sodium chloride and potassium metabolism (E. S. R., 24, p. 172).

The pathogenesis of pellagra, H. Raubitschek (Wiener Klin. Wochenschr., (1916), No. 26, pp. 963-965).—The results are presented of an experimental study of the effects of exposure to sunlight upon maize-fed animals with reference to a possible relation to the etiology of pellagra (see below).

Concerning the pathogenesis of pellagra, H. Raubitschek (Centbl. Bakt. [etc.], 1. Abt., Orig., 57 (1911), No. 3, pp. 193-208).—Experiments are reported on the effects of an alcoholic extract of maize when fed to animals exposed to sunlight (see below).

Pellagra and its possible relation to maize according to some recent views, C. H. Lavinder (Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Rpts., 26 (1911), No. 8, pp. 199-208).—A digest of data is presented particularly of investigations by Raubitschek (see above), which have to do with the effects of sunlight upon animals fed Indian corn in association with the question of a possible relation to the etiology of pellagra, the work being a contribution to the study of the wholesomeness of corn as food. The data presented concern the possible relation between pellagra and the occurrence of a photodynamic substance in Indian corn.

In general, the author cited believes that he has demonstrated the presence of such material in corn. An alcohol-soluble substance of this character was isolated from maize and its effects studied in experiments with animals. From his experiments Raubitschek concludes that "a diet of maize (good or bad), when administered under the influence of sunlight, is deleterious to white mice, and that in this we have relations closely analogous to what is seen in fagopyrismus," and further that "by alcoholic extraction of maize meal (removal of fat) the active body is removed, and hence for this reason extracted polenta, free of fat and color stuffs, even under the influence of sunlight, is not directly harmful as a food."

He states further that he does not attempt to bring his experimental results into a strict relation with the etiology of pellagra or to assume for it a photodynamic basis, or even to conclude that this disease is produced by an almost exclusive diet of maize, good or bad, which displays its harmful effects first under the influence of light. It is pointed out that the results are to be considered as very suggestive but not yet conclusive.

The distribution of extractives in mammalian muscles, O. von Fürth and C. Schwarz (Biochem. Ztschr., 30 (1911), No. 6, pp. 413-432).—Horse and dog flesh were used in the investigations reported as to the distribution of the different nitrogenous constituents in muscular tissue.

In a comparison of normal and fatigued muscle the authors did not observe any marked variation from the usual distribution of such constituents. In general, they conclude that creatin and especially carnosin are the most abundant of muscle extractives. The desirability of further physiological studies of carnosin is pointed out.

The relation of brain phosphatids to tissue metabolites, W. Koch and W. W. Williams (Jour. Pharmacol. and Expt. Ther., 2 (1910), No. 3, pp. 253-264).—According to the authors, the observation that the accumulation of potassium in the cell can be more satisfactorily explained by the fact that it is combined with kephalin, than on the theory of any hypothetical semipermeable membrane, should be capable of extension to tissue metabolites. The
tendency of a tissue metabolite to accumulate in and also to be eliminated from the cell in which it has been manufactured; "its ability when eliminated from the first cell to enter into and accumulate in other cells or to be immediately excreted through the kidney, no doubt bears some relation to its power of combination with tissue colloids. . . . Specific chemical affinities very probably play a rôle and the present investigation was undertaken to determine to what extent the phosphatids possess the power of combining with products of tissue metabolism."

Some of the conclusions follow, which were drawn from experiments with substances which may be regarded as of food value to the tissues, including amino acids, glycocoll, and glucose, and with substances having a characteristic physiological action, including among others adrenalin, caffeine, and theobromin:

"The changes in state of aggregation of lecithin produced by sodium chlorid are the result of the independent action of the sodium and chlorin ions, whose effects are in opposite directions. Below the concentration of a physiological salt solution (0.12 molecular) the action of the chlorin ion, which decreases the state of aggregation of the lecithin, predominates. Above the concentration of a physiological salt solution, the action of the sodium ion, which tends to increase the state of aggregation of lecithin, comes more and more into prominence.

"It has been suggested that, when the phenomenon of chlorid retention occurs, some change has taken place in the state of aggregation of the cell lipoids which allows this action of the chlorin ion to predominate to a still greater extent.

"Ammonia and bile salts possess the power of altering the physical state of aggregation of lecithin to such an extent as to permit of the conclusion that they can be of functional significance in altering the permeability of cell membranes. . . .

"The ability of the tissue metabolites to combine with lecithin, as measured by the changes in the physical state of aggregation produced by their presence, is in some cases considerable, in other cases entirely lacking. Thus hypoxanthin, creatin, creatinin, adrenalin, and ammonia salts show evidence of combination. Inosit is doubtful and urea is negative.

"The amino acids show varying powers of combination. The dicarboxyacids, like acids in general, tend to increase the state of aggregation of lecithin."

The relation between surface area and respiratory exchange, H. Kettner (Die Bezeichnungen der Körpereberfläche zum Respiratorischen Gaswechsel. Inaug. Diss., Univ. Bern, 1909, pp. 30, pls. 2, fig. 1).—According to the author's investigations, which were made with young and with older guinea pigs, total carbon dioxid production increases with increased body weight and increased surface area, differences being very much greater when expressed on the percentage basis per unit of body weight. The experimental data reported are discussed in relation to theories of nutrition.

ANIMAL PRODUCTION.

The mineral nutrients in blue grass, E. B. Forbes, A. C. Whittier, and R. C. Collison (Ohio Sta. Bul. 222, pp. 39-53).—A study of the nutritive value of the mineral constituents of blue grass (Poa pratensis), with special reference to the content of phosphorus and the chemical condition in which it is present.

Blue grass from different localities varied greatly in its content of mineral elements, some pastures in Ohio containing twice as much mineral nutriment as others. Samples at all stages of growth from Ohio and Kentucky varied in
calcium between 0.135 and 0.424 per cent, in potassium between 1.41 and 2.43 per cent, and in total ash between 4.8 and 8.32 per cent. "Those samples which were richest in phosphorus were from pastures which were heavily fertilized by the excreta of animals grazing upon them. In one such pasture the grass contained 0.463 per cent of phosphorus, on a dry-matter basis, while on a thin clay hilltop the grass contained only 0.164 per cent of phosphorus. The organic phosphorus content of these grasses was generally highest where the total phosphorus was highest, and where the grass had been heavily fertilized. The next to the highest figure of all for organic phosphorus accompanies a medium total phosphorus content in a field of grass which had been twice fertilized with a complete commercial fertilizer. . . . Thus we may conclude that the organic phosphorus may be increased by manuring and the use of complete fertilizers, but not to so great an extent as the inorganic phosphorus."

The analyses of blue grass grown on experimental plots showed: "(1) That the grass fertilized with sodium phosphate contained more phosphorus than any other; (2) that the grass fertilized with potassium chloride contained more potassium than any other; (3) that the grass fertilized with lime contained more calcium than any other; (4) that the grass fertilized with a mixture of the three compounds contained more ash than any other grass; (5) that the excess of phosphorus in the grass fertilized with sodium phosphate over that present in the unfertilized grass was all in an inorganic condition; that is, the addition of sodium phosphate to the soil did not increase the percentage of phosphorus-containing proteins in the blue grass; (6) that the use of the phosphate as a fertilizer appeared to increase the potassium in the grass, and conversely the use of the potassium salt as a fertilizer increased the phosphorus in grass; (7) that the use of lime was without noticeable effect on either the potassium or the phosphorus in the grass; and (8) that the addition of potassium chloride to the soil increased to a marked extent the organic phosphorus of the grass, while sodium phosphate and lime were without effect on this constituent."

Analyses showed that the phosphorus was higher in the plants grown with an abundance of water than in those grown in a dry place. It is stated that this may have been only a coincidence and a further study is necessary on this point. To further test the effect of moisture, oat plants were grown in pots in greenhouse, and the following results were obtained from an analysis of plants cut at various times: "The percentages of moisture, ash, and phosphorus in the oat plant vary in an orderly way according to the amount of moisture available during growth. The nature of the effect of increased soil mixture depends, in a measure, on the stage of growth of the plant. In the early stages of growth of oats increased moisture increases to a slight extent the percentages of moisture and phosphorus in the plant."

Canadian blue grass (P. compressa) was found to be somewhat more woody than the common blue grass. It was richer in potassium but less so in nitrogen, calcium, and phosphorus, and is probably not so valuable a feed.

Some practical conclusions drawn from this work are the following: "It seems likely that the organic phosphorus in blue grass is present in sufficient amount to sustain normal growth of animals, but the need for inorganic phosphorus is much greater, and on infertile pastures we may be able to grow better bone, at least, by feeding calcium phosphate. Calcium phosphate may be fed ad libitum, mixed with salt, or it may be fed mixed with the ration. It may also be indirectly administered by using on the pastures fertilizers containing calcium and phosphorus. For growing or milk-giving animals we would give about ⅓ lb. of bone flour per 100 lbs. of air-dry feed."
Indian cane as a fodder and stand-by, A. H. Haywood (Agr. Gaz. N. S. Wales, 22 (1911), No. 1, pp. 79-81, fig. 1).—This includes favorable comments by stock farmers concerning the use of Indian cane as a fodder plant in Australia. An analysis of the cane grown on the volcanic soil of the Grafton experiment farm, made by F. B. Guthrie, is as follows: Moisture 69.60, albuminoids 2.25, ether extract 0.19, carbohydrates 10.08, fiber 6.84, and ash 11.04 per cent.

The feeding value of mangels, T. B. Wood (Proc. Cambridge Phil. Soc., 16 (1910), No. 1, pp. 42, 43).—After studying the data of feeding trials which included about 400 animals, A. B. Bruce found that the probable error in the case of 1 animal amounted to 14 per cent of the average increase in weight during the feeding period. From this it is concluded that it is necessary to make comparative tests with at least 25 animals, each receiving the same ration, in order to be able to get a really significant result.

One hundred or more varieties of mangels were reduced to 5 types, namely, the White Fleshed Globe, Intermediate, Golden Tankard, Golden Globe, and Long Red. The latter yielded 3.9 tons of dry matter per acre, or more than half a ton per acre more than any of the other types.

Feeding experiments were made by Professor Middleton in order to ascertain the feeding value of these types of mangels in proportion to their content of dry matter. In a series of 7 trials 2 lots were fed side by side on rations containing equal amounts of cotton or linseed cake and chaff, but 1 lot received the White Fleshed Globe mangels and the other an equal quantity of Long Reds. It was found that the increases in live weight were in the proportion of 100:116±4 in favor of the Long Red. By using 90 animals the probable error was brought inside the difference which was under measurement. The difference found being 4 times the probable error of the experiment, it is therefore concluded that there is probably at least 10 per cent in real difference in feeding value in favor of the Long Reds.

Two other trials in which the Golden Tankard and Long Red were compared, each containing equal percentages of dry matter, were found to be well inside the probable error. “The result of 2 sets of trials is to make it practically certain that the percentage of dry matter in mangels may be taken as an index of their feeding value.”

[Notes on protein hydrolysis in feeding stuffs], F. W. Foreman (Proc. Cambridge Phil. Soc., 16 (1910), No. 1, pp. 87, 88).—It is suggested that considerable economy might be effected by purchasing feeding stuffs the proteins of which were known to be rich in the groups in which the proteins of home-grown feeds are deficient. In order to accomplish this it is necessary to ascertain the nature of the proteins in the commercial feeding stuffs.

The author submits a preliminary report on the proteins of linseed, which were determined by hydrolysis of the crude protein. The results are as follows: Alanin 1.03, valin 12.71, leucine and isoleucin 3.97, prolin 2.85, phenylalanin 4.14, aspartic acid 1.65, glutaminic acid 11.58, tyrosin 0.65, arginin 6.06, histidin 1.66, lysin 1.19, ammonia 1.94 per cent. Glycin, serin, and tryptophan were also present but not in measurable quantities. It is thought that the low tyrosin content may be due to the method used. The customary method is considered unsatisfactory, and the subject is to be further investigated.

Condimental feeds, stock and poultry tonics and conditioners, G. M. MacNider (Bul. N. C. Dept. Agr., Jan., 1911, Sup., pp. 38).—Analyses are given of a large number of condimental feeds for stock and poultry, together with the text of the state law in regard to these feeds.

Inspection of commercial feed stuffs, P. H. Smith et al. (Massachusetts Sta. Bul. 136, pp. 3-56).—This bulletin reports analyses of commercial feeding
stuffs, and presents a discussion as to their relative values, calling attention to desirable and undesirable feeding stuffs for Massachusetts conditions. Among other matters of interest to the purchaser of feeding stuffs is a tabulated list of the wholesale cost of feeding stuffs for the year 1910.

The analyses include cotton-seed meal, linseed meal, gluten feed, distillers' dried grains, malt sprouts, brewers' dried grains, wheat middlings, wheat mixed feed, wheat bran, rye feeds, calf meal, corn meal, molasses feeds, ground oats, rye meal, hominy meal, provender, fortified starchy feeds, corn bran, dried-beet pulp, meat scrap, bone meal, cut clover, alfalfa meal, and proprietary mixed feeds.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 786, p. 1; 794, pp. 3; 798, p. 1).—These relate to the misbranding of stock feed and the adulteration and misbranding of cotton-seed meal.

Profitable stock raising, C. A. Shamel (New York, 1911, pp. IX+274, pls. 7, figs. 21).—This book treats of the profitable types of all classes of live stock, and discusses the broad problems involved in the live stock industry.

[Live stock in East Friesland], Wegner et al. (Deut. Landw. Tierzucht, 15 (1911), No. 10, pp. 109-123, figs. 20).—A series of articles by different authors and a report on the present condition of the live stock industry, together with a discussion of some influences at work for the improvement of the different kinds of farm animals in East Friesland.

The breeds of the most important domesticated animals in Africa, D. Kürchhoff (Tropenpflanzer, 11 (1907), No. 8, pp. 550-559; 12 (1908), Nos. 3, pp. 129-135; 7, pp. 328-335; 11, pp. 524-531; 13 (1909), No. 5, pp. 222-228; 14 (1910), No. 6, pp. 302-308).—The characteristics of the native breeds of horses, cattle, sheep, and swine are described. Considerable historical matter is included, as well as methods of feeding and managing as practiced in the different countries. There are numerous references to the literature.

Transportation of domesticated animals by water, J. Zinke (Der Transport von Haustieren zur See, Ivanp. Diss., Univ. Bern, 1910, pp. 89).—This contains an outline of the history of ocean transportation of animals, and discusses the construction and equipment of vessels and the loading, feeding, and treatment of animals during transport.

A bibliography is appended.

The identification of animals by branding and otherwise, P. A. Fish (N. Y. State Vet. Coll. Circ. 2, pp. 16).—Comments on different methods of branding and the effect on hides.

Some modern large foreign abattoirs, H. Martel (Hyg. Viande et Lait, 4 (1910), Nos. 11, pp. 577-609, figs. 5; 12, pp. 616-665, figs. 5; 5 (1911), Nos. 1, pp. 1623, fig. 1; 2, pp. 87-96; fig. 1).—The plans and equipment of large abattoirs in Dresden, Zurich, Vienna, and Stuttgart are illustrated and described, with special reference to sanitary condition.

The bamboo wattle silo, B. Coventry (Agr. Jour. India, 6 (1911), No. 1, pp. 20-26, pls. 6).—A silo constructed of bamboo wattle, covered on the side with a plastering of mud and provided with a light roof of thatch, is illustrated and described.

The Lincolnshire red Shorthorn breed of cattle, G. E. Collins (Rhodesia Agr. Jour., 8 (1911), No. 3, pp. 398-403, pls. 4).—A general account of the characteristics of this breed and its adaptability for South African conditions, as judged by the importations which have already been made.

95157°—No. 1-11—6
The Odenwälder cattle, DÜNKELBERG (Deut. Landw. Tierzucht, 15 (1911), No. 11, pp. 123-128, figs. 4).—The value of this breed of cattle is pointed out, and the methods of management in its native district are discussed.

Cattle breeders' associations in Denmark, F. RASMUSSEN (U. S. Dept. Agr., Bur. Anim. Indus. Bul. 129, pp. 40, pls. 2).—This contains a brief history of the Danish cattle industry and the plan and organization of cattle breeders' associations, with special reference to their usefulness to the dairy industry. The method of judging bulls at shows, the market prices of bulls and conditions of transfer, and other matters of interest to dairymen are given. The appendix contains the by-laws for cattle breeders' associations under common management on the island of Funen, the law relating to institutions for the promotion of the breeding and keeping of domestic animals, and the form of contract used in the purchase of bulls.

Uniformity of growth in calves, A. GOUIN and P. ANDOUARD (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 11, pp. 445-447).—The percentages of nitrogen and phosphoric acid retained in the body increased with the age of the calf, whereas the daily increase in weight did not change materially with the age.

Raising beef cattle in Alabama, D. T. GRAY and W. F. WARD (Alabama Col. Sta. Bul. 150, pp. 3-21, figs. 5).—This is a discussion of the advantages of the South as a beef-producing region, and a report of a test made by the station in cooperation with the Bureau of Animal Industry of this Department to test the cost of raising grade Angus steers to the feed-lot period under southern conditions. During the summer months no feed was given in addition to the pasture, which consisted principally of white clover, Bermuda, and Lepedea. In addition to the winter range, hay and cotton seed were fed. The hay consisted of a mixture of sorghum, crab grass, Johnson grass, and cowpeas, and was not of good quality. Green sorghum was used for several days at one time to supplement a short pasture.

During the summer the calves made an average daily gain of 1.24 lbs. each, the yearlings 1.22 lbs. each, while with the older stock the gains were not so large. During the winter the calves gained 0.29 lb. per day, while the yearlings and older stock lost in weight. "An average of the whole year shows that the calves made a daily gain of 0.77 lb. or a total gain of 276 lbs. per head. The yearlings made a daily gain of 0.564 lb. per head, or a total of 203 lbs. for the 12 months. A gain of 170 lbs. per head, or a daily gain of 0.47 lb., was made by the cattle while they were increasing from 24 months to 30 months in age, while 135 lbs., or 0.4 lb. per head per day, was made by the animals while they were increasing in age from 24 to 33 months."

The cost per hundredweight of raising a steer, when the manure received no credit, was estimated as follows: To 12 months of age $5.07, to 24 months of age $4.84, to 30 months of age $4.95, and to 33 months of age $4.90. It is stated that these gains might be made cheaper if the cattle had been free from ticks and a combination of clover and Bermuda pasture had been used to lengthen the pasture season.

Wintering steers in Alabama.—Fattening cattle on pasture in Alabama, D. T. GRAY and W. F. WARD (Alabama Col. Sta. Bul. 151, pp. 25-63, figs. 16).—Continuing the work noted above, the object of the experiments reported in this bulletin was to test the methods of finishing steers after they had reached the feed-lot period. The stock used were grades containing Angus, Shorthorn, Hereford, and Red Polled blood, and many with a predominance of Jersey and scrub breeding. The summer pasture consisted of a mixture of sweet clover, Japan clover, Johnson grass, and some Bermuda. The winter range consisted of the winter corn and cotton fields.
The winter feeding was continued for 2 seasons. In the winter of 1907-8 each range steer which received no supplementary feed lost on an average 97 lbs. and in the following winter 106 lbs. in weight. The lot receiving cotton-seed meal and hulls as an additional ration lost 6 lbs. per head the first season and gained 3 lbs. per head the second season. The cost of the extra feeds for these lots was $4.70 and $5.63, respectively. With good pennine hay as a supplementary feed, at a cost of $3.57 per head, the average loss was 9 lbs. each. With cotton seed as a supplement, costing $3.23 per head, the loss was 40 lbs. per steer. With cheap hay as a supplementary feed, costing $2.60 per head, the loss was 40 lbs. each.

The steers used in the winter work, noted above, were redivided and continued for summer feeding. In 1908 the lot on pasture alone made an average daily gain of 1.52 lbs. per head, at a cost of 1.18 cts. per pound gain, dressed 49.5 per cent live weight, and made a profit per steer of $2.86. The lot receiving cotton-seed cake in addition to pasture made an average daily gain of 2.32 lbs. per head, at a cost of 2.56 cts. per pound gain, dressed 53.8 per cent live weight, and made an average profit per steer of $10.42. With caddo cake (cold-pressed cotton-seed cake) as a supplement the average daily gain was 1.84 lbs. per head, at a cost of 3.03 cts. per pound gain, dressed 53.6 per cent live weight, and made an average profit of $6.52 per steer. A second lot of scrub stock, receiving cotton-seed cake, made an average daily gain of 1.92 lbs. per head at a cost of 3.24 cts. a pound gain, dressed 52.7 per cent live weight, and made an average profit of 43 cts. per head.

In 1909 the lot without supplementary feed made an average daily gain of 1.74 lbs. per head, at a cost of 1.03 cts. per pound gain. This lot dressed 51.8 per cent live weight, and made an average profit of $7.06 per steer. The lot receiving cotton-seed cake made an average daily gain of 1.88 lbs. per head at a cost of 3.24 cts. per pound gain, dressed 54.2 per cent live weight, and made an average profit of $6.39 per steer. A lot receiving cotton seed as a supplement to pasture made an average daily gain of 2.06 lbs. per head at a cost of 2.39 cts. per pound gain, dressed 53.9 per cent live weight, and made an average profit of $8.39 per head. Those given feed in addition to pasture lost less in transport than the rest. The extremely low profit of one lot receiving cotton-seed cake was due to the fact that they were scrubs, varying from 1 to 5 years in age.

From these tests it is apparent that it pays to supplement southern pastures with a concentrated feed when cattle are being finished for the fall market, that cotton-seed cake was superior to the cold-pressed cake, and that the whole cotton seed produced cheaper gains than the cotton-seed cake. Additional tests are promised to determine what concentrated feeds can be used to the greatest advantage.

**Feeding experiments with steers and hogs, J. T. Cruse (Texas Sta. Bul. 135, pp. 25, figs. 8).—This bulletin reports tests of rations with cotton-seed meal in connection with various supplementary feeds for steers and hogs.**

Cotton-seed meal, rough red rice, and unheaded and unshredded Kafir corn was fed to 2 lots of 8 steers for 34 days, in which an average daily gain of 1.76 lbs. per head was made. Fully 50 per cent of the Kafir corn passed through undigested. The rice was fed unground and had a tendency to cause bloating and scouring. The ration was then changed to ground rough red rice, cotton-seed meal, Johnson grass hay, and corn chops. The average daily gain made on this ration for 34 days was 2.35 lbs. per head, at a cost of 8.56 cts. per
EXPERIMENT STATION RECORD.

During the remainder of the 90-day period 4 of the steers received cold-pressed cotton-seed cake and Johnson grass hay, and made a gain of 1.25 lbs. per head and day, while the other 4 steers on cotton-seed meal and hulls gained 0.85 lb. per head and day.

Another lot of 8 steers on cotton-seed meal and Kafir corn forage for 34 days, and then on cotton-seed meal, rough red rice, and cotton-seed hulls for 56 days, made an average daily gain of 2.7 lbs. at a cost of 9.16 cts. per pound. A lot on cotton-seed meal, rough red rice, and Johnson grass hay during the entire 90 days gained 2.19 lbs. per head and day, at a cost of 12.29 cts. per pound. A ration of cotton-seed meal and hulls for 90 days produced an average daily gain per head of 2.44 lbs., at an average cost of 8.72 cts. per pound.

Block tests showed that the last lots were superior to the others in quality of meat, although the percentage of dressed weight was less. Though Kafir corn forage proved unprofitable, it is thought to be an economical feed if fed with the heads ground and the stalks shredded. When the price of Johnson grass hay is reasonably low it is recommended as a roughage for fattening steers, but none of the feeds at the prices estimated in the bulletin can economically take the place of cotton-seed meal and hulls.

The pig feeding tests were made with grade Poland-Chinas, Duroc Jerseys, and Berkshires. There were 5 lots of 10 pigs each, and the average gains per head and day were as follows: On cotton-seed meal and corn chop, mixed and fermented, 1.8 lbs. at a cost of 4.56 cts. per pound; on cotton-seed meal and unground rough red rice, mixed and fermented, 1.4 lbs. at a cost of 5.74 cts. per pound; on tankage and unground rough red rice, mixed and fermented during the larger portion of the period, 1.28 lbs. at a cost of 7.6 cts. per pound; on alfalfa meal and rough red rice (most of the time ground), mixed and fermented, 1.26 lbs. at a cost of 8.08 cts. per pound; on alfalfa meal and corn chop, fermented, 1.14 lbs. at a cost of 11.02 cts. per pound.

These results show that ground rough red rice fed with cotton-seed meal is an economical ration for fattening hogs. The lots receiving most nearly the standard ration made the largest and most economical gains. At no time during the experiments was there any injurious effects from feeding cotton-seed meal.

Pig feeding experiments and two kinds of hog houses, A. L. Stabler (Maryland Sta. Bull. 150, pp. 93-132, figs. 11).—This bulletin reports feeding tests with pigs, and describes two styles of hog houses in use at the station.

The first feeding trial was with 10 Poland-Chinas divided into 2 equal lots. One lot, on a ration of ground corn fodder, in 3 months made an average daily gain of 0.573 lb. at a cost of 6.88 cts. per pound. A lot on corn and cowpea slilage ad libitum gained 0.73 lb. per head and day, at a cost of 6.51 cts. per pound. In a comparison of shelled corn and corn meal fed in connection with skim milk somewhat better gains were made than with corn meal alone, but this advantage was offset by the higher cost per pound of gain.

Comparison was made of wet, soaked, and dry feeds when the ration consisted of corn-and-cob meal, wheat middlings, and gluten meal. In a trial lasting 112 days a lot receiving the grain in the form of a thick slop by mixing with water or milk made an average daily gain per head of 0.623 lb., at a cost of 7.82 cts. per pound. When the feed was mixed and allowed to soak 24 hours before feeding, the gain per head and day was 0.759 lb., at a cost of 6.63 cts. per pound. The lot fed dry grain made an average daily gain per head of 0.713 lb., at a cost of 0.87 cts. per pound.

In another test when chopped alfalfa was added to a ration of shelled corn and wheat middlings, the gains were reduced the first part of the period but increased the latter half. In a feeding test with wheat bran substituted for
one-fifth its weight of hominy chop, the value of the ration was increased, but hominy chop alone gave better results than a mixture of 3 lbs. of hominy chop and 2 lbs. of bran.

A test of hopper feeding was made, in which 5 Duroc Jerseys were allowed access at all times to corn meal, wheat bran, tankage, and linseed meal. The nutritive ratio of the voluntary ration was 1:7.3. More corn meal was eaten than all other feeds combined. The pigs ate regularly without surfeiting and produced pork economically. A patent motor grinder and feeder gave good results in 2 tests, but when used in comparison with hopper feeding with both shelled corn and corn meal the margin of profit was in favor of the hopper-fed pigs.

A tonic mixture (E. S. R., 6, p. 661), wood charcoal, and soft coal were compared as correctives and were ranked in value in the order named. The pigs fed the soft coal in large quantities had better appetites and gained more than pigs having no corrective. A hog house containing 5 pens and a portable hog cot are illustrated and described.

Cost of raising pigs, C. A. Wilson (Wallaces' Farmer, 36 (1911), No. 12, p. 56j).—An experiment in the cost of producing and growing pigs up to the time of weaning is reported.

The average cost of maintaining the sow was $11.66, besides 15.5 cts. for maintaining the boar. The birth charge for each pig therefore varied from $11.82, when there is only one in the litter, to 74 cts. when there is a litter of 16. To these figures must be added $1.87 for the feed of the sow in order to determine the total cost to the time of weaning.

Influence on the production of mutton of manures applied to pasture, W. Somerville (Jour. Bd. Agr. [London], 17 (1911), No. 10, Sup. 5, pp. 58, pl. 1).—A summary of trials begun in 1896, brief reports of which have appeared from time to time (E. S. R., 15, p. 597).

Some of the conclusions drawn from the work as a whole are the following:

"Cake of various sorts was fed to sheep on pasture at 11 centers, and in no instance was the outlay on the cake recovered in the increased mutton produced by the sheep in the season when the cake was consumed. . . . Common burned lime, used alone at the rate of 4 tons per acre, has proved very ineffective; but smaller dressings of ground lime, when added to a phosphatic dressing, have sometimes been justified. . . . Where a direct comparison has been made between the effects of equal quantities of phosphoric acid derived from basic slag and superphosphate respectively, the former manure has always produced the greater amount of live weight increase. When the cost of manure is taken into account, the profits from the use of basic slag have always been much greater than those from superphosphate.

"Potash added to a phosphatic dressing generally resulted in the production of more live weight increase, but this increase was not a profitable one. The expediency of using potash on pastures—as contrasted with meadows—therefore, receives no support from these experiments. The addition of moderate dressings of sulphate of ammonia or nitrate of soda to land already treated with phosphatic has increased the yield of herbage, but has, as a rule, reduced the yield of mutton. . . . Dissolved bones compare badly with basic slag and superphosphate."

Fundamental facts about wool, C. S. Plumb (Breeder's Gaz., 59 (1911), No. 14, p. 884).—The structure of the wool fiber and the grades of wool found on the market are explained.

Hygroscopic qualities of wool (Bul. Nat. Assoc. Wool Manfrs., 40 (1910), Nos. 2, pp. 128-151, figs. 5; 3, pp. 209-217, figs. 2; 41 (1911), No. 1, pp. 108-118, pls. 9).—This is a discussion of the properties of wool fibers by H. Priestman
and W. D. Hartshorne. Some experimental data on the textile qualities of wool fiber are reported.

On the wool track. C. E. W. Bean (London, 1910, pp. XVII+296, pls. 8, fig. 1).—The contents of this book were originally written as a series of articles for the Sydney (Australia) Morning Herald. The Australian wool industry from the paddock to the loom and the life of the sheep herder in the back country are depicted in a vivid style.

Phases of the wool trade (Breeders Gaz., 59 (1911), No. 10, p. 630).—A consideration of some factors concerned in the process of conveying wool from the shearing pen to the buyer of woolen goods, in which it is pointed out that the system of distribution is expensive and burdensome alike to grower and consumer.

The need of more wool (Bul. Nat. Assoc. Wool Manfrs., 40 (1910), No. 1, pp. 11-23).—An editorial containing statistical data on the production and consumption of wool in the United States. The opportunities for wool growing, especially in New England and on the western ranges, are pointed out.

The evolution of a breed (Live Stock Jour. [London], 73 (1911), No. 1928, p. 270).—This refers to the new breed known as Polo pony, which has been brought about by crossing the Thoroughbred with several kinds of ponies. In 12 years' time a type has been produced which combines in a remarkable degree the height and hardiness of the pony with the speed and stamina of the Thoroughbred, and which apparently breeds fairly true to type.

Iceland horses, Becker (Lundc. Umschau, 1910, No. 46, pp. 1134, 1135; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intl. and Plant Diseases, 1910, No. 2, p. 312).—A note on the increase in the use of Iceland horses in Denmark, where they have proved to be excellent farm horses, being both hardy and resistant to disease. There are about 45,000 horses in Iceland, and from 3,000 to 4,000 are exported yearly to Denmark, England, and Scotland.

The stud farms of Bâbolua, Nemeth (Rev. Hongric, 1910, No. 5; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intl. and Plant Diseases, 1910, No. 2, p. 312).—An account of the work of the Hungarian Department of Agriculture in encouraging horse breeding by maintaining a large number of pure-bred stallions, one-fifth of which are Arabs.

[Stallion regulation] (Jour. Bd. Agr. [London], 17 (1911), No. 12, pp. 1029, 1027).—This contains the regulations of the Board of Agriculture and Fisheries of Great Britain for the registration and service of stallions.

Recommendations regarding stallion laws (Breeders Gaz., 59 (1911), No. 8, p. 497).—These recommendations, which were adopted by the executive committee of the National Society of Record Associations, are suggested for those States where there is a desire to amend existing laws or to formulate new laws concerning the registration of stallions.

Horses and riding, E. L. Anderson (Fort Leavenworth, Kans. 1909, pp. 68, pl. 1, figs. 40).—This contains instructions for riding and training horses, with a brief description of breeds of horses best suited for the saddle.

Harness, harness fitting and repairing, A. H. E. McDonald (Agr. Gaz. N. S. Wales, 21 (1910), Nos. 11, pp. 917-953; 12, pp. 1028-1035; 22 (1911), No. 1, pp. 39-47, figs. 26).—This series of articles, which was prepared for the use of farmers, treats of the troubles caused by ill-fitting harness, the uses of the different parts, and the care and repair of the harness and other horse trappings.

Laboratory outlines for the study of the embryology of the chick and the pig, F. R. Lillie (Chicago, 1906, 2. cd., pp. 50).—The methods of study em-
ployed in these outlines are (1) a study of the living embryo, (2) a study of the entire embryo as an opaque object with a dissecting microscope and with the compound microscope, after killing, hardening, staining, clearing and mounting, (3) a study of embryos by dissection, and (4) studies of serial sections by the microscope.

The transformations in the fats in the hen's egg during development, Elizabeth C. Eaves (Jour. Physiol., 40 (1910), No. 6, pp. 451–453).—The increase of fat in a chick was not as rapid as the decrease of fat in the yolk. The iodin values showed that there was a change in the composition of the fat, and presumably the oxidized fat was used to furnish energy for the growing embryo.

"During the first 10 days the iodin value of the yolk fat did not vary much; it decreased from 70 to 64. After this there was a marked decrease, the value fell from 64 to 43.7. The iodin value of the chicken fat was at first low, 59.4 to 61.1. This may be due to the presence of other substances in the fat obtained; in the early stages the amount of fat extracted was very small, and it contained a relatively large proportion of the brown substance which is very soluble in water and insoluble in water-free ether, but soluble in wet ether; this brown substance is probably glyceral and glycerophosphoric acid. As development proceeds the iodin value rose and after the fifteenth day was considerably higher than that of the fat from a fresh yolk. Just as in the case of the phosphorus compounds the most marked changes occur between the thirteenth and twentieth days, the maximum being reached just before the chick is hatched. The decrease in the iodin value in the yolk fat is suggestive of a primary absorption of the less saturated fats with a subsequent equal absorption of saturated and unsaturated fat. The increase in the iodin value of the chicken fat points to a desaturation of the absorbed fat."

The action of X-rays on the developing chick, J. F. Gaskell (Proc. Roy. Soc. [London]. Scr. B, 83 (1911), No. 564, pp. 305–310).—When incubating eggs were exposed to the action of X-rays the mitotic activity of the growing tissue was lowered, an effect which was very evident in embryos exposed to long doses, as no mitotic figures could be found in an embryo of 3 days when exposed for 4 hours. Diminution was progressive even with small doses, but if not too great complete recovery occurred. The critical dose which prevents recovery varied with the stage of the development of the embryo, decreasing as the mitotic figures decreased. No other microscopic nor macroscopic changes were observed.

Data on the relative conspicuousness of barred and self-colored fowls, R. Pearl (Amer. Nat., 55 (1911), No. 530, pp. 107–117, figs. 4).—Statistics are presented which cover the hatching season of 1909 at the poultry plant of the Maine Station. These show that though barred birds were relatively much less conspicuous than birds of one color, the relative inconspicuousness of the barred color pattern did not afford its possessors any great protection against elimination by natural enemies.

The White Orpington color problem, G. D. Black (Rel. Poultry Jour., 18 (1911), No. 2, pp. 232–269).—Some possible causes of brassiness (fading of the feathers) in white breeds are suggested. The author does not think that it is induced by the nature of the feeds, but on the other hand supposes it to be some physiological condition that may be bred out.

Forcing egg yield by use of artificial light, W. H. Reynolds (Rel. Poultry Jour., 18 (1911), No. 2, pp. 240, 241, 263–264, figs. 4).—A report of an experiment in lengthening the "working hours" of hens in the winter season by turning on an electric light an hour before daylight and after dark. The egg yield
was increased and no ill effects noted. The yield dropped in 4 days after the light was discontinued.

Poultry raising and the increased price of meat, K. Wagner (Fricks Rundschau, 1910, Nov. 5; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intell. and Plant Diseases, 1910, No. 2, p. 318).—It is suggested that instead of offering money prizes at poultry shows the prizes should be distributed among poultry farmers undertaking to put a certain number of fowls and eggs on the market every year at fixed prices, and to those raising the best 4-month chickens and 8-month hens for breeding. Other measures recommended for encouraging the poultry industry are leasing of pasture lands, granting of subsidies to poultry societies, and offering more poultry courses in agricultural schools.

The white laced red Cornish fowl, W. H. Caed (Rel. Poultry Jour., 18 (1911), No. 2, pp. 236, 265-267, figs. 2).—An account of the origin and characteristics of a comparatively new breed that was not a chance creation but “a variety whose every characteristic was thought out and attained after persistent effort and intense study of the laws of nature regarding feather markings and undercolor that are in harmony with popular market requirements, also the laws of nature regarding egg production and flesh properties.”

The Indian Runner duck book, C. S. Valentine (Ridgewood, N. J., 1911, pp. 89, figs. 8).—A practical work written to supply information on this variety of duck, which has recently become very popular.

Darwinism, biometry and some recent biology, I. K. Pearson (Biometrika, 7 (1910), No. 3, pp. 368-385).—A discussion of the elimination of the unfit, the inheritance of the somatic characters on which fitness depends, and the absence of differential fertility.

Recent papers by Pearl (E. S. R., 21, p. 372), Jennings (E. S. R., 21, p. 469), Lloyd (E. S. R., 22, p. 672) and others are reviewed, and it is stated that there is no justification for the conclusion of these authors that selection has no effect within the pure line. It is also maintained that the only way in which it can be determined whether selection within the pure line is effective is to compare the correlation of the offspring with both parents and grandparents in a parthenogenetic species. In the only cases in which this has been done the parental correlation is greater than the grandparental, which would indicate a cumulative effect of selection.

The correlation between horn and hoof development, G. Heerwagen (Deut. Landw. Tierzucht, 14 (1910), Nos. 17, p. 193; 12, pp. 397, 398).—The author criticizes the findings of Laurer (E. S. R., 23 p. 174) on the ground that there was too wide a variation within the group, that the age of the animals was not considered, and that not enough animals were measured to warrant drawing definite conclusions.

[The correlation between horn and hoof development], G. Laurer (Deut. Landw. Tierzucht, 14 (1910), No. 29, pp. 349-352; 15 (1911), No. 6, pp. 62-66).— Replies to the criticism noted above.

The function of the corpus luteum (Jour. Amer. Med. Assoc., 56 (1911), No. 8, pp. 555, 556).—An editorial which summarizes recent work, from which it is evident that secretions of the corpus luteum affect the sexual cycle. One important function seems to be the prolongation of the length of time between two successive ovulations. The secretion sensitizes the uterine mucosa so that it reacts to any sort of mechanical stimulus toward forming the maternal

---

*For references to recent studies on the histology of the corpus luteum and the secretions of germinal glands of both sexes of different animals see Zentbl. Gesam. Physiol. u. Path. Stoffwechsel, n. ser., 6 (1911), No. 5, pp. 214-224.
placenta. Up to the present time negative results only have been obtained in the attempt to produce the characteristic effect of the secretion under normal conditions by injecting extracts of the fresh corpus luteum.

On the differences in metabolism of rabbits' ova and their significance in the sex problem, A. Russo (Biol. Centbl., 31 (1911), Nos. 2, pp. 51–58, figs. 5; 6, pp. 177–182, figs. 3). Further details are given concerning the two kinds of ova (E. S. R., 23, p. 472), as an answer to the author's critics.

Creating new animals and plants, W. J. Spillman (Sci. Amer., 104 (1911), No. 7, pp. 164, 165, 184, 185, figs. 11).—Examples are given of the way in which Mendel's law may be used to improve domesticated animals and plants.

Transmission of white in horses, W. E. Castle (Breeder's Gaz., 59 (1911), No. 15, p. 9/8).—A note on a white stallion which is a heterozygous dominant.

An estimate is given of the probable nature of his offspring.

On the influence of hybridizing on the form, color and markings of canary eggs, A. von Tscharmak (Biol. Centbl., 39 (1910), No. 19, pp. 641–646).—Female canaries were crossed with the siskin, linnet, goldfinch, bullfinch, and other wild birds. In length, breadth, and form the eggs had the characteristics of the mother, whereas the color of the shell was frequently the color of the shell of the species to which the male belonged.

A partial index to animal husbandry literature, C. S. Plumb (Columbus, Ohio, 1911, pp. 94).—This bibliography of books, articles, and experiment station publications on animal husbandry was prepared with blank leaves so that other useful titles might be added. "It is limited in the number of titles, but many of the references are quite available, consequently the list should be serviceable. The titles of many of the books are given in considerable detail, thus indicating the nature of the contents. Occasional brief comments are made by the writer on the value and standing of certain books, bulletins or articles."

DAIRY FARMING—DAIRYING.

Studies of the protein requirements of dairy cows, F. W. Woll and G. C. Humphrey (Wisconsin Stat. Research Bul, 13, pp. 175–216).—This reports a study of the milk records and character of the rations fed to the university dairy herd for a period of 9 years.

The method of management of the herd and records of the individual cows has been previously noted from time to time. Throughout the period there has been a general improvement of the herd, but there have been marked variations in each period when the system of feeding followed has been nearly uniform. After making due allowance for these disturbing factors, however, the results show that the production of the cows on high protein rations was in general lower than that on medium protein rations. The average for periods A and C, when the medium protein ration was fed, was 321.66 lbs. of butter fat per head per year, as against 307.9 lbs. for period B when a high protein ration was fed.

"The total value of the products per year per cow was, for periods A and C $87.15, and for period B, $80.49, a difference of $6.66 in favor of the medium protein rations. The cost of the feed was for periods A and C $38,
and for period B $38.72; the net profit per cow per year for the different periods was therefore as follows: Period A, $44.39, period C, $53.90; average of periods A and C, $49.15; period B, $41.77, a difference of $7.38 per cow annually, or 17.7 per cent in favor of the medium protein rations.

"In spite of the fact that the high protein rations cost somewhat more, on the average for the herd than those medium in protein, more milk and more butter fat were produced on the latter and about 18 per cent larger net profit per cow was obtained on the average for the respective periods of the investigation."

"While the general results of this investigation lead to the conclusion that the exact amount of protein required in the feeding of dairy cows is less important than was formerly believed to be the case, it is nevertheless certain that a liberal supply of protein is necessary for the production of large amounts of milk and butter fat; it can be readily shown, in fact, that there is a direct relation between the production of total solids or butter fat and the amounts of digestible protein fed or the nutritive ratios of the rations fed dairy cows. . . . The larger the production, the more feed the cows eat, and the narrower the nutritive ratio becomes."

"The teachings of the investigation described in this bulletin tend to emphasize the importance of farm-grown feeds for dairy cows."

Milk records, analyses, and cost of feeds, and an estimate of feed requirements for cows of different weights and productive capacity, are presented in tabular form.

The selection of feeds for dairy cows, F. W. Woll and G. C. Humphrey (Wisconsin Sta. Bul. 206, pp. 3–17).—A brief and popular discussion of the feeding of dairying cows, based largely on data reported in the bulletin noted above.

The separate inheritance of quantity and quality in cows' milk, J. Wilson (Sci. Proc. Roy. Dublin Soc., n. ser., 12 (1910), No. 35, pp. 470–473, dgmns. 6).—Using the data of the Ayrshire Cattle Milk Records Committee (E. S. R., 23, p. 780), the author submits diagrams intended to show that there is no correlation between quality and quantity in milk.

Note on the separate inheritance of quantity and quality in cows' milk, K. Pearson (Biometrika, 7 (1910), No. 4, pp. 538–550).—The article noted above is criticized because of the clubbing together of tall frequencies, and because the diagrams failed to show the independence of quality and quantity of milk. The mean percentages and the variation in fat of the 4 groups of Wilson were estimated by the author, with the following results:

Mean percentages and variations of fat in milk of Ayrshire cattle.

"For the whole population of 2,866 cows the mean is 3.672 and the variability is measured by 0.323. It will accordingly be clear that there is (1) a slight but perfectly definite decrease in quality with increase of quantity, the low-yielding cows having a higher, the high-yielding cows a lesser fat percentage than the average Ayrshire, although the increase and decrease only amount to
about 1 per cent of the average yield, and (2) the variation in quality is not the same for cows of each quantity category. Cows which give high quantity have far less variation in their yield of butter fat than cows of low yield. The number of cows is so large relatively that the probable errors are small and there is no doubt about the results being significant. Owing to the manner in which the tails of the above frequency have been clubbed together it is not possible to work out the proper correlation by the ordinary product moment method. The means, however, suggest that the correlation can not be very far from linear, and the correlation ration $\eta$ may be fairly taken to measure $\tau$. This gives us $\tau = -0.075$ with a probable error of 0.013, a result, if small, yet indefinitely significant."

The dairy cow and her record, W. K. Brainerd (Virginia Sta. Circ. 8, pp. 23, figs. 7).—This contains information for the practical dairymen as to how the unprofitable cow can be weeded out by weighing the milk and testing for fat.

Abnormal milk secretion. Barrowsky (Deut. Landw. Tierzucht, 15 (1911), No. 6, pp. 61, 62).—A citation of cases where milk has been secreted in males and in females of different species of animals before conception.

On the accidental presence in milk of sulphocyanids and their origin, Stocklin and Crochetelle (Compt. Rend. Acad. Sci. [Paris], 159 (1910), No. 23, pp. 1530, 1531).—Milk from cows fed linseed cakes showed the presence of sulphocyanids. Analysis of the cake showed that it contained oil of mustard, which apparently was converted into sulphocyanid in the organism and thence transferred to the milk. Evidently the cakes had been adulterated with products of cruciferous plants.

The action of the medical officer of health in dealing with milk supplies affected by outbreaks of sickness among cows, H. Stott (Jour. Roy. Sanit. Inst., 32 (1911), No. 1, pp. 20–26).—A brief discussion of the different diseases which are liable to be spread by contaminated milk. The duties of health officers in the event of a milk-borne epidemic are pointed out.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment, 787, 788, p. 1 each).—These relate to the adulteration of milk.

The bacterial content of separator cream and separator milk, P. G. Heine- mann and E. Class (Jour. Amer. Pub. Health Assoc., 1 (1911), No. 3, pp. 209, 210, pl. 1).—A continuation of earlier work (E. S. R., 22, p. 478). The object of these experiments was to determine whether the amount of fat and cream bore any relation to the bacterial counts, and also whether a definite relation could be established with the bacterial content of the separator milk.

"Separator cream contains smaller numbers of bacteria than the milk from which it is obtained. The number of bacteria in separator cream decreases proportionately as the fat content increases. The number of bacteria in separator milk is larger than the number in the milk from which it is obtained if the cream contains up to about 35 per cent fat. Above this percentage the number is smaller. The number of bacteria in separator milk decreases proportionately with the increase of fat in the separator cream."

On the Bulgarian ferment, J. Effront (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 8, pp. 463–465).—A note on a species of bacterin obtained from milk soured with the Bulgarian ferment, which behaves quite differently from the species usually found in medicinal preparations of milk ferment in that it acts
feebly upon casein and is strongly acidifying, though the percentage of volatile acids is relatively small.

The bacteriology of "tätté melk," P. S. Heinemann (Scienc, n. ser., 33 (1911), No. 851, p. 630).—This favorite food in Scandinavia is made by inoculating sweet cow's milk with the leaves of butterwort (Pinguicula vulgaris), which causes the milk to become thick and slightly stringy and with a slight cheesy taste and odor.

A microscopical examination of the samples showed streptococci in large numbers, mostly in diplococcus form. Two species of yeast were abundant, one being oval and the other a large organism with square ends, often forming long filaments. There were also some bacilli resembling Bacillus coli in shape and size, which proved to be gram-negative. There were a few large bacilli, resembling that group commonly found in milk and which forms larger amounts of acid than ordinary lactic-acid bacteria.

A study of plate cultures was made, and the different organisms isolated. "The streptococcus could not be distinguished microscopically from Streptococcus lacticus, but its action on sterile milk differed, in that it coagulated but slowly; after coagulation the coagulum was stringy, similar to the coagulum formed by B. bulgaricus, but in a smaller degree. The oval yeast gave the microscopic picture of Saccharomyces cerevisiae. It ferments lactose and saccharose with violent gas production, levulose slowly, and maltose not at all. Cultures of this yeast in liquid beerwort impart a somewhat stringy consistency to the medium. The other yeast proved to be Oidium lactis, which is always present in milk and in this milk is probably responsible for a slight cheesy taste and odor."

The fresh cheeses are carried to the dairies, where they are pricked with a needle and rubbed with salt to prevent a rapid fermentation. They are then placed on shelves and covered with a layer of salt, which is occasionally renewed, for 3 or 4 months or until no more salt is absorbed. The forms are then covered with a paste made of olive oil, suet, and kaolin to prevent drying. The process requires at least 2 curing houses, one underground where the temperature is about 12° C. at the first period of the salting and for the last period of the ripening process, and another at a temperature between 15 and 18° for the second salting period and the drying of the cheese by the elimination of the whey.

Géromé cheese, A. Rolet (Lait, et Indus. Ferme [Paris], 21 (1911), No. 3, pp. 17-19).—A description of the method of making Géromé cheese, also called Gérardmer (and sometimes, although incorrectly, Munster), which is extensively made in the department of Vosges.

The water supply and the removal of the waste water of creameries, F. Guth (Gesundhts. Ingen., 34 (1911), No. 9, pp. 163-165).—A lecture before the International Congress of Agricultural Associations at Brussels, September, 1910. The chemical and biological properties of the water supply of creameries and the disposition of wastes are discussed.

Creamery bookkeeping, M. Mortensen (Iowa Sta. Bul. 121, pp. 306-322).—A complete system of bookkeeping is outlined, the object being to present a
VETERINARY MEDICINE.

Upon the real immune state and the question of immunity in infectious diseases, E. METCHNIKOFF (In Les Prix Nobel. Stockholm, 1908, pp. 1-24).—This is the author's address before the Nobel Prize Committee at Stockholm in 1908.

In regard to the partial functions of the cell, P. EHRLICH (In Les Prix Nobel. Stockholm, 1908, pp. 1-19).—This is the author's address before the Nobel Prize Committee at Stockholm in 1908, and deals particularly with his newer work in chemotherapy.

Hematological technique, H. SCHRIDDE and O. NAEGEI (Hämatologische technik. Jena, 1910, pp. VI+135, pl. 1, figs. 20).—The first part of this work, on the technique of histological methods of studying the blood and blood-forming organs, is by H. Schridde; the second part, on the technique in clinic-morphological studies of the blood, is by O. Naegeli.

Contribution to the study of the physiology of Spirillum gallinarum.—I, Assimilation of glucose, A. PONSELLE (Compt. rend. Soc. Biol. [Paris], 69 (1910), No. 30, pp. 307-309; abs. in Chem. Abs., 5 (1911), No. 3, pp. 519, 529).—It was found in experiments with this organism in vitro that the assimilation and loss of motility process makes use of the glucose in the blood of the host for glucolysis. The blood, according to the author, contains a catalytic agent which aids in the assimilation of the glucose, the glucose not being assimilated directly by the organism.

The supposed catalytic agent is resistant to a heat at 110° C., this only for a few minutes. Oxygen was found to be necessary for the reaction, which progresses slowly at 15° and rapidly at 37°. It was found that the liver also contains the catalytic substance, and could be substituted for the red blood corpuscles. The spirillum dies in a few minutes at 37°, unless calcium carbonate is present to neutralize the acids in formation.

Cultivation in vitro of the thyroid gland, A. CARREL and M. T. BURROWS (Jour. Expt. Med., 13 (1911), No. 4, pp. 416-421, pls. 3).—The authors find that "the thyroid gland in mammals can be cultivated outside the body. The proliferated elements consist of connective tissue and epithelial cells, the former predominating. The cells survive in cultures for 2 weeks or longer, which period can be increased by secondary and sometimes by tertiary cultivations."

Contribution to the study of bacterial filtrates and extracts, T. KIKUTSI (Beiträge zum Studium der Bakterienfiltrate und der Bakterienextrakte. Diss. Osaka, 1910; abs. in Ztschr. Immunitätisf. u. Expt. Ther., II, Ref., 3 (1910). No. 11, p. 985).—Bouillon filtrates and aqueous extracts from agar cultures of various pathogenic and saprophytic bacteria did not yield any soluble, thermostable, bactericidal substances, with the exception of Bacillus pyocyaneus. Some of the bactericidal substances of B. pyocyæneus were found in the filtrates, while others were only present in the watery extracts. The thermostable substance which was extracted with alcohol is, according to the author, a lipoid-protein combination, and is only broken up when the bacterial substance is treated with alcohol, and then only is its bactericidal action manifest. Normal bovine and sheep sera and human ascitic fluid produced precipitates with bacterial extracts or filtrates. This precipitation does not occur when the serum or ascitic fluid is heated to 60° C.
The relation between the protein of woman's milk to that of the serum protein in mother and child, A. Bauereisen (Arch. Gynäkol., 90 (1910), No. 2, pp. 349-393; abs. in Zentral. Allg. u. Expt. Biol., 1 (1910), No. 4-5, pp. 159, 160).—The author studied this problem from 3 view points: (1) The relation of the proteins among themselves and to the serum protein of the mother; (2) the relation of the milk proteins to the protein of the blood serum of the new-born; and (3) the relation of the colostrum proteins to the serum of the new-born, as determined with the aid of biological and biochemical methods.

The analysis of the antigens showed that the protein content of the mother serum was 8.15 per cent; of the colostrum 8.41 per cent; that obtained from the serum of the umbilical cord of the new-born contained 5.5 per cent, while the whey protein had only 0.42 per cent. The biological results with the precipitin reaction showed that the constitutional specificity is very definite with casein, but that a close relation is also seen between the colostrum protein, the whey protein from the milk which follows, and the serum protein of the mother. It was further found that the blood serum of the new-born which has not suckled contains the same antigens as that of the mother but in a lesser quantity, since the mother's serum contains more true protein.

The author finally presents the hypothesis that the more living protein the individual has the greater is his resistance. On the basis of his findings as to colostrum proteins, the author points out the enormous importance of colostrum in the nutrition of the young, and gives biological, chemical, historical, and evolutionary data to demonstrate this.

The value of the mouse-feeding test for meat inspection, Kempa (Berlin. Tierzücht. Wechselr., 26 (1910), No. 40, pp. 785-787).—The results point to the fact that the mouse-feeding test can easily be eliminated in judging meat for human consumption. Total reliance can be placed on the bacteriological method (E. S. R., 22, p. 183; 23, p. 183).

The xiphoid lymph-gland, Stroh (Ztschr. Fleisch u. Milchhyg., 20 (1910), No. 8, pp. 249-252, figs. 2; abs. in Vct. Rec., 23 (1911), No. 117, pp. 423, 424).—The author describes a lymph-gland which he has discovered in the angle formed by the cartilage of prolongation of the last sternal rib and the sternum which is of importance in meat inspection work.

The xiphoid lymph-gland of Stroh, P. Godbille (Hyg. Viande et Loi, 4 (1910), No. 12, pp. 633-638, figs. 4; abs. in Vct. Rec., 23 (1911), No. 117, pp. 423, 424).—The author gives an account of the anatomical relations of the xiphoid lymph-gland mentioned in the account noted above and gives directions for exposing it. The gland, which varies from the size of a pea to that of a haricot, is not constant, being found upon an average in 6 out of 10 subjects.

Meat inspection at Karlsruhe, Mannheim, and Ludwigshafen, P. Brandt (Volksw. Abhandl. Bad. Hochsch., 9 (1908), No. 6, pp. 141).—Slaughtering, inspection of meat, and similar matters are discussed with special reference to the localities under consideration.

Live stock sanitary laws of the State of Arkansas, W. Lenton (Arkansas Sta. Bul., 106, pp. 351-366).—This bulletin includes the text of the state live stock sanitary laws, the regulations of the board of control of the station, the governors' proclamations in regard to county quarantines, and federal quarantine regulations applicable to Arkansas, together with notes on these laws and regulations.

Report of the bacteriologist, C. E. Marshall (Michigan Sta. Rpt., 1910, pp. 150-152, 160-179).—In order to test the danger of tuberculosis from apparently healthy animals that reacted to tuberculin, several pigs of about 50 lbs. weight were kept in contact with 2 cows for periods of from 66 to 82 days. The pigs failed to develop the disease, and this was also the case with guinea pigs, in-
jected with bouillon suspension of feces, and with a calf that sucked one of the cows. Upon slaughtering the cows only a few slight calcified and encapsulated lesions of the bronchial lymph glands and lungs were found in one; while in the other the right bronchial glands were greatly enlarged, the tubercular mass showed calcareous degeneration, and the right cephalic lobe of the lungs contained a large tubercular mass undergoing liquefaction.

A tabular report is given of herds treated with hog-cholera serum during the years 1908 to 1910. Studies made by Giltner of the cellular elements of the blood of hyperimmune hogs show that "the successive weekly bleedings lessen the number of erythrocytes in proportion as the number of bleedings increases. In most cases the number of leucocytes is decreased. The decrease in number of leucocytes is due to a constant decrease in large mononuclears, and a nearly constant decrease in lymphocytes and eosinophiles while this disease is only partially offset by a nearly constant increase in polyonuclears and mast cells. There may be a slight temporary increase in the number of erythrocytes per cubic centimeter immediately after bleeding. There is a tendency for both the actual numbers and the percentages of lymphocytes to decrease and of polyonuclears to increase immediately after bleeding. Changes in the staining properties of the erythrocytes may result from repeated bleedings of serum hogs. The changes noted in this connection are in harmony with what has been observed by others in studying the effects of hemorrhage on the cellular elements of the blood."

Tests made with lactic-acid cultures for irrigation in contagious abortion and other diseases in an attempt to find a substitute for the ordinary coal tar and chemical antiseptics are briefly described. Investigations made of an outbreak of disease among sheep in Kent County resulted in the discovery of the stomach worm (*Hamonchus contortus*) to be the cause. Small numbers of the whipworm (*Trichocephalus affinis*) were found in the cecum and small nodules due to *Esophagostoma columbianum* in the intestinal walls. In 1 lamb examined many of the bronchioles in the dorsal portion of both principal lobes of the lungs were filled with lungworms (*Strongylus vulgaris*). Notes are given on a disease of cattle near Kinde, Huron County, which was not considered to be of an infectious or parasitic nature, several cases of hemoglobinuria in horses near Laingsburg, and a wasting disease of horses at Inlay City.

Eighth annual report of the state board of live stock commissioners of Ohio, 1908-9, P. Fischer et al. (Ann. Rpt. Ohio Bd. Agr., 64 (1909), pp..659-698, figs. 19).—The occurrence during the year of stock diseases is briefly reported upon.

Annual report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, for the year 1909-10 (Ann. Rpt. Bengal Vet. Col. and Civ. Vet. Dept., 1909-10, pp. 1-7+1-12+VIII+2).—The annual report of the Bengal Veterinary College, by F. Raymond (pp. 1-7) includes accounts of the occurrence of epizootic diseases in Calcutta and vicinity, and of the work of the research laboratory. The report of the Civil Veterinary Department is by D. Quinlan (pp. 1-12).

In the reports on contagious disease it is stated that the total mortality among equines and bovines was 386 and 17,645 respectively, against 391 and 16,456 the previous year. Glanders was responsible for the death of 160 equines. Tabulated data show rinderpest to have killed 8,899, foot-and-mouth disease 2,374, hemorrhagic septicemia 3,130, black quarter 737, and anthrax S12, bovines. The report includes an account of preventive inoculations against rinderpest, only 93 of 12,549 animals having died after inoculation.

Investigations in regard to putrefaction products which are bactericidal to the anthrax bacillus, K. Stein (Arch. Wiss. u. Prakt. Tierheilk., 36 (1910),
No. 6, pp. 634-651).—It appears from this work that bacterial-free filtrates from putrefying animal cadavers contain a heat-stable bacteriolytic enzyme (for the anthrax bacillus) which has its optimum at 37° C. The enzyme content of the putrefying material was found to vary with the degree of putrefaction—the further the putrefying process proceeds, the lower the enzyme content will be. The enzyme can be precipitated with Nessler’s reagent and hydrochloric acid, but not with tannic acid.

A lethal infection with putrefying anthrax material for experimental animals was not possible, because the virulence had already been disturbed before inoculation. The enzyme was also not capable of checking an already existing anthrax bacteremia in mice. As the putrefying anthrax-bactericidal material was in itself toxic, it was not possible to protect against a subsequent infection with anthrax bacteria.

[Anthrax outbreak on university farm], H. L. Russell (Wisconsin Sta. Bul. 293, pp. 7-9).—This is a brief description of an outbreak of anthrax in the university herd and the manner in which it was handled. The general opinion that hogs do not acquire anthrax unless fed on anthrax-infected carcasses was found to be erroneous, as it is concluded that the death of several hogs in the herd must have come from soil infection.

The specific cure of yaws with dioxydiamidoarsenobenzol. R. P. Strong (Philippine Jour. Sci., B. Med. Sci., 5 (1910), No. 4, pp. 433-431, pls. 14).—Reports are presented of 25 cases of yaws or frambesia treated with salvarsan. This drug appears to be an ideal specific for the disease. “Three or 4 days after the injection of the drug, the granulomatous lesions begin to disappear and in the course of from 10 to 20 days they usually have disappeared entirely leaving a perfectly smooth, pigmented skin where the lesions previously existed.”

The treatment of yaws (frambesia) with arsenobenzol (salvarsan). R. P. Strong (Jour. Expt. Med., 13 (1911), No. 4, pp. 412-415, pls. 2).—A preliminary account of the investigations reported in the article noted above.

The curative effect of salvarsan (“606”) in cases of frambesia, H. Alston (Brit. Med. Jour., 1911, No. 2616, pp. 360, 361).—The author finds that the serum of patients treated with salvarsan is capable of producing an improvement in other cases of yaws not less marked than that produced by the drug itself, also that the serum of the patients thus treated with serum possesses the same property. Control experiments show that it is essential that the serum be derived from a patient suffering from yaws and that the serum be taken when the patient is under the influence of salvarsan.

The curative effect of salvarsan in frambesia, H. Alston (Brit. Med. Jour., 1911, No. 2629, p. 618).—“The experiments in Trinidad have contributed to knowledge in 4 directions: (1) The serum of cases recovering under salvarsan has been shown to have a curative effect; (2) nostril yaws tubercles are not affected by salvarsan nor by serum; (3) the milk of a goat injected with salvarsan has a curative effect; and (4) soamin and orsudan are the only organic compounds—excluding salvarsan, of course—that cause some benefit in yaws.”

The complement fixation reaction of rabies, N. A. Dorbowolskaja (Centbl. Bakl. [etc.], I. Abt. Orig., 56 (1910), No. 2, pp. 177-183).—As a result of immunizing dogs against rabies, bodies are produced in the blood which give a definite complement binding or fixation reaction with specific antigens. The reaction, according to the author, for the present has no practical significance, because at times it can be produced with nonspecific antigens. An effort to determine specific substances (with brain substance from rabid animals) in the blood with the reaction resulted in showing that a positive test could also be obtained with the blood from normal dogs at the height of digestion.
An investigation into scabies in laboratory animals, R. C. Low (Journ. Path. and Bact., 15 (1911), No. 3, pp. 333-348, pls. 9).—The author here presents a short description of the appearances, methods of diagnosis, the course usually run, and measures to be taken to prevent the spread of scabies among laboratory animals.

Tetanus, P. F. Bahnson (Amer. Vet. Rec., 38 (1911), No. 4, pp. 502-510).—This article deals particularly with the treatment of tetanus in animals.

An attempt to cure toxicosis of pregnancy with the serum from pregnant subjects, A. Mayer and Linsé (Münch. Med. Wochenschr., 57 (1910). No. 52, pp. 2757-2759, figs. 2; abs. in Ztschr. Immunitätsf. u. Exp. Ther., 11, Ref., 5 (1910), No. 11, p. 932).—A general review of the theories of toxicosis of pregnancy is given, after which the authors present a hypothesis that the condition is due to the presence of foreign proteins in the mother's blood, and an absence of the corresponding antibodies. The presence of an increased antitryptic index, an activated cobralysin, and peptolytic enzymes favors this hypothesis.

The authors describe a case of herpes gestationis in a woman, who was treated with 30 cc. of a serum obtained from another pregnant subject. A rapid resolution of the disease took place.

The detection of tubercle bacilli in the circulating blood. S. ACS-NAGY (Gyögyászat, 28 (1910), July, pp. 491-496; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 4 (1910), No. 12, p. 629).—The author found tubercle bacilli in the blood stream of 24 human tuberculous subjects. The work shows that tubercle bacilli can also occur in the blood stream when the process is a localized one.

About the intravenous inoculation of mice with human and bovine tubercle bacilli, R. Trommsdorff (Arch. K. Gesundtsamt., 32 (1909). No. 2, pp. 563-573).—According to the author, no work is at hand in regard to the intravenous inoculation of mice with tubercle bacilli. In this investigation he utilized the tail vein, and in the article gives the technique in detail.

The results show that with the human type of tubercle bacillus not a single mouse died, nor did the animal on autopsy show any indication of the disease. On the other hand, where the bovine type of tubercle bacillus was inoculated the animals became tuberculous. The author points out the possibility of utilizing the mouse for differential diagnosis.

Enzootic of avian tuberculosis, which was possibly of human origin, DARMAGNAC (Rec. Méd. Vét., 86 (1909), No. 15, pp. 504-506).—The author describes cases of avian tuberculosis in chickens and a turkey, some of which were killed for human food. He discusses the possibility of its having its origin from man.

The Ninth International Tuberculosis Conference, REGENER (Ztschr. Tuberkulose, 16 (1910), No. 6, pp. 690-695).—The ninth conference was held at Brussels, October 5 to 8, 1910. It was organized in 4 sections, which discussed respectively the following topics: (1) Clinical and experimental studies (discussed by Messrs. Landouzy of Paris, Williams of London, Aufrecht of Mag-

95157°—No. 1—11—7
deburg, and Raw of Liverpool); (2) protection of children against tuberculosis (discussed by Messrs. Bielefeldt of Lubeck, Bruck of Berlin, Rördam of Copenhagen, Pynappel of Zwolle, and Hamel and Nietner of Berlin); (3) tuberculosis and the school (discussed by Messrs. Altschul of Prague, Fronz of Vienna, Gumprecht of Weimar, Jacob of Berlin, and Patrikios of Athens); and (4) combating tuberculosis by women (discussed by Dr. Lefèvre of Genablonx, Mrs. Altschul of Prague, Mrs. Girard-Mangin of Paris, Mrs. Pannwitz of Charlottenburg, Mrs. Pischinger of Lohr, and Mrs. Pynappel of Zwolle, and the Misses Possaschnain of St. Petersburg, Sommer of Bern, and Chaput of Paris).

Malignant diseases in bovines, A. M. Trotter (Jour. Compar. Path. and Ther., 24 (1911), No. 1, pp. 1-20).—The results are reported of an inquiry undertaken to ascertain the age, sex, and organ incidence of disease in bovines affected with malignant neoplasms.

The cultivation of the organism of chronic bovine enteritis, Albien (Berin. Tierärztl. Wcnschr., 26 (1910), No. 41, pp. 793, 794).—A polemical article in which the author (E. S. R., 20, p. 581) replies to Messner, and in which he gives the formula of the glycerin-agar medium (nutrient, Hayden from 5 to 10 gm., agar from 10 to 20 gm., glycerin from 20 to 30 gm., sodium chloride 5 gm., a normal solution of sodium carbonate crystals (28:100) 5 gm., and distilled water 1,000 gm.) on which the above organisms will grow. See also a previous note (E. S. R., 22, p. 287).

A minute on the cattle disease, R. Willmot (Agr. and Stock Dept. Tasmania, Bul. 19, 1910, pp. 15, pls. 8).—This is a preliminary account of chorea paralytica bovis, commonly known in Tasmania as “the cattle disease.”

Observations and researches on enzootic hematuria of bovines, Korschann (Österr. Monatsschr. Tierhilk., 1910, Nov.; abs. in Rev. Gén. Méd. Vét., 17 (1911), No. 197, p. 287).—Piroplasmosis due to *Piroplasma bigeminum*, transmitted by *Ixodes ricinus*, occurs in Hungary along the Carpathian range. Acute and prolonged cases occur from time to time but usually the disease does not last longer than a week. The mortality is said to be low, not rising above 10 per cent.

Acute contagious mastitis in cows due to the Bacillus lactis aerogenes, J. A. Gilruth and N. Macdonald (Vet. Jour., 67 (1911), No. 430, pp. 217-223).—“*B. lactis aerogenes*, while not pathogenic by inoculation into the tissues of cattle, may yet cause acute inflammation if introduced into the lactating udder of cows. Such an infection may be readily spread by milking machines. The bacilli after the first few days of infection may be so few as to be overlooked. The secretion, although originally favorable to the growth of bacteria, rapidly assumes an inhibitory power. There is evidence that the blood serum itself rapidly becomes antitoxic.”

The preparation of antirinderpest serum by means other than the injection of virulent blood, F. S. H. Baldrey (Jour. Trop. Vet. Sci., 6 (1911), No. 1, pp. 1-20, pl. 1, charts 21).—The author concludes “that the method of employing peritoneal washings to augment the amount of inoculable virulent material is a good one. It produces an antirinderpest serum of a high value, but less potent than that produced by blood inoculation. In comparison with serum from blood inoculations it is of great value in the less susceptible plains animals than in the highly susceptible hill cattle. Its reaction is produced principally by a toxin which is rapidly formed under the vital influence of the peritoneal cavity.”

Stiff-sickness or stijfziekte in cattle, A. Theiler (Agr. Jour. Union So. Africa, 1 (1911), No. 1, pp. 10-21, pls. 4).—“The disease ‘stiff-sickness’ in

cattle resembles in all respects laminitis in horses, in fact it may be called 'laminitis in cattle.' Experiments undertaken at 2 different places, Barberton and Zeerust, 1 in the eastern and 1 in the western part of the Transvaal under opposite climatical and tellurial conditions, show that *Grolitiaura burkeana* is the cause of stiff-sickness.*

Some neglected sheep diseases of New South Wales, M. Henry and A. E. Massy (Agr. Gaz. N. S. Wales, 22 (1911), No. 2, pp. 109-117, map 1).—The authors here record what is known of so-called black disease, louping ill, and staggers, in order to demonstrate the need of further investigations and to serve as a basis for such.

**A minute on sheep diseases, R. Willmot (Agr. and Stock Dept., Tasmania, Bull. 16, 1910, pp. 16).—**The author here considers braxy and louping ill.

**Johne's disease in sheep, S. Stockman (Jour. Comp. Path. and Ther., 24 (1911), No. 1, pp. 66-69, fig. 1).—**The author considers the observations here reported to justify the statement “that sheep may under natural conditions become infected with Johne's disease and that this animal must now be considered a factor in the epizootiology of this affection. They do not, however, warrant the conclusion that the disease known as 'scrapie' is a form of Johne's disease, as it is possible, of course, that 2 different diseases may sometimes affect the same animals.”

**Serovaccination against hog erysipelas, Scholl (Rev. Gén. Méd. Vét., 16 (1910), No. 182, pp. 65-69).—**This is a report of serovaccination work against hog erysipelas in Belgium. In 1906 there were 4,870 vaccinations and in 1909, 84,806. The results obtained were excellent.

**Hog cholera, L. Van Es (Amer. Vet. Rev., 38 (1911), No. 4, pp. 489-501).—**A discussion of the etiology, symptoms, pathology, and serum treatment of this disease.

**The swamp fever of horses, J. L. Todd and S. B. Wolbach (Jour. Med. Research, 24 (1911), No. 1, pp. 213-242, 4gm. 1).—**The results are given of observations on 7 cases of swamp fever, 5 cases of which were artificially produced by direct inoculation. In this work the symptoms and the gross pathological and histo-pathological findings of the organs are reported. All the subjects with one exception came to autopsy.

The ring bodies of Ballah were noted in all the horses, but similar bodies could be seen by the authors in the liver of a normal dog. Sarcosporidia and *Sclerostomum equinum* or *S. tetracanthum* were almost always present.

According to the authors, the cases were too few in number to make it possible to draw definite conclusions from them. The results do not differ from those obtained by previous observers; consequently, the observations will merely serve to confirm those of others who have preceded them in studying the disease. A bibliography is appended.

**The chemotherapeutic treatment of equine influenza, Rirs (Berlin, Tierärztl. Wochenschr., 27 (1911), No. 7, p. 113).—**When a single injection of a full dose (0.01 gm. per kilogram of body weight) of a warm to blood-warm, dilute alkaline solution of salvarsan (Ehrlich-Hata 606) was given to a horse in the first stages of influenza, it was noted that this remedy could easily cope with the progress of the disease. Three gm. of salvarsan in 1,500 gm. of solution was generally found sufficient for a horse of medium weight. The later stages of the disease are also favorably influenced by this remedy.
Periosteotomy in spavin, J. J. Wester (Tijdschr. Vetartsenijk., 36 (1909), No. 15, pp. 913-926; abs. in Vet. Rec., 23 (1910), No. 1152, pp. 84, 85).—After having employed a majority of the usual methods of treating spavin the author has finally given preference to periosteotomy. His method of operation, which is a modification of that of Peters, is described in detail.

Symbiotic otacariasis of the cat, J. W. Kalkus (Amer. Vet. Rec., 39 (1911), No. 1, pp. 53-56. fig. 1).—The occurrence in the State of Washington of several cases of auricular acariasis is reported. The first cases are said to have appeared in cats brought to this country in 1908 from the Isle of Man.

A sarcoma of the fowl transmissible by an agent separable from the tumor cells, P. Roux (Jour. Expt. Med., 13 (1911), No. 4, pp. 397-411, pls. 6, figs. 2).—In the experiments reported small quantities of the cell-free filtrate were sufficient to transmit the growth to susceptible fowls.

RURAL ECONOMICS.

The cost of living, H. P. Fairchild (Pop. Sci. Mo., 78 (1911), No. 4, pp. 377-380).—Maintaining that the price of foodstuffs is determined by the law of supply and demand and the proportion between those who produce and those who consume, the author attributes the cause of increased price of food commodities in the United States to the preponderance of the urban population. He asserts that the greatest total wealth of society can be produced only when the efforts of the agricultural classes are supplemented by those engaged in certain vocations of the city, and points out that there is a point in the economic development of a country when the number of those engaged in the city becomes excessive.

He questions whether that point has been reached in the United States. He shows that for every inhabitant in 1790 in cities of more than 8,000 population there were 28 persons living in the smaller towns and country districts; 50 years later there was one city dweller to 11 country dwellers; in 1890 the proportion had reached 1 to 3.4; and in 1900 1.2.

With this condition of affairs it would be supposed that owing to the high price of farm products there would be large profits to the farmer, country life would be more attractive, and the rush to the city checked. However, it is observed that the large excess over the actual cost of production does not find its way back to the pockets of the producers but is absorbed by transportation companies, commission merchants, packers, and retail dealers.

Prices of farm products to producer and consumer, James Wilson (U. S. Dept. Agr. Rpts. 1910, pp. 19-26).—This report shows that the price received by the farmer for agricultural products is not exorbitant, and is much below that paid by the consumer. The wide difference in prices is attributed to the existing system of marketing farm produce, and it is shown that of every dollar the consumer pays for poultry, potatoes, fruit, dairy products, and some other necessaries, the producer receives on an average about 53 cts., the railroad company about 7 cts., and the middlemen about 40 cts. Other illustrations are given showing the costliness of the system under which farm products are transferred from farmer to consumer, and it is pointed out that part of the cost could be eliminated by substituting cooperative selling associations on the part of the farmers, and direct buying or cooperative buying by the consumer from these cooperative selling associations.

Current agricultural wages (Amer. Agr., 87 (1911), No. 13, p. 536).—In addition to other statistics relative to farm labor the article gives a table
recently compiled by the tariff board showing the average amount of wages paid by the day or month to farm laborers in the United States and Canada in 1899. It is shown that the average monthly rate of wages to farm hands without board in the United States in 1910 was $27.50 as compared with $18.33 in 1890.

Mathematical distribution of wages, O. Ballauff (Illus. Landw. Ztg., 31 (1911), No. 11, pp. 85, 86).—The author, after discussing the economic significance of the division of labor, deals more specifically with the subject of computation and mathematical distribution of wages as related to the various divisions of the operation of agricultural products, and determining the limit and application of wages as to the various operations of production. He goes into the subject of farm accounting, shows the possibility of having a careful and exact method of reckoning wages, and discusses the merits and defects of the different systems upon which wages are paid. The piecework system is considered the simplest and most practical and has the advantage of inducing the laborer to greater performance.

Report of the select committee on agricultural cooperation (Rpt. Select Com. Agr. Coop. [Cape Good Hope], 1907, pp. XVIII+52).—In addition to the testimony and other evidence collected by a special committee appointed to investigate the workings of agricultural cooperation and the advances made by the government for that purpose, the report states the findings and recommendations of the committee. Out of £55,491 11s. 8d. advanced during the period under review to various organizations and groups of individuals £11,652 15s. 2d. was advanced to wineries; £32,125 17s. 8d. to creameries; £7,275 to fencing syndicates; £1,959 to preserving companies; £595 18s. 2d. to boring syndicates; £575 to thrashing syndicates; and £130 11s. 2d. to live stock improvement syndicates.

The report shows that there is a lack of cooperation on the part of applicants for loans and that the government has made advances out of all proportion to the pecuniary interest of the members of the associations. In an illustration cited the government advanced £11,000, and the actual cash payments by shareholders of the cooperative society amounted to only £101, or less than 1 per cent of the sum advanced by the government.

The committee recommends that the government should not encourage or assist any society unless it is satisfied with the proposed management; that the loans should not exceed the face value of the issued capital, at least 25 per cent of which should be paid up before any loan is advanced; and that moneys loaned should be used in connection with operating expenses and not in payment of outstanding debts.

While the committee finds that misfortunes have befallen some of the efforts in cooperation it is of the opinion that the utility of the movement has been established and that farmers in their own interest will have to continue to develop it.

A traveling bank for farmers, D. G. Ricard (Agr. Econ., 44 (1911), No. 496, p. 91).—The article states that in order to induce the farmers in the up-country districts of the Cape and Transvaal and Orange River Colony to appreciate the advantage and safety of depositing their money in the care of a bank, a system of banking by motor car is in full operation. “The cars are fitted with a safe and desk, and the clerk in charge of the car receives deposits and pays out in checks. A regular route is arranged so that the people know when to expect the car. The cars call at the doors of the farmhouses ‘for orders.’” The farmers at first manifested a great deal of distrust, but it is noted that this is gradually giving way.
The Jewish Agricultural and Industrial Aid Society (Jewish Agr. and Indus. Aid Soc. Ann. Rpt. 1909, pp. 65).—The report gives a history and summary of the work done by the Jewish Agricultural and Industrial Society since its organization. In a review of the work of the society for the last 10 years it is shown that during 1900-9 loans were made aggregating $14,425, and in 1909 there were 256 loans aggregating $141,494.48. The total amount of loans made during the 10 years aggregates nearly $800,000, and is distributed in Canada and 24 States of the United States.

Farm bookkeeping, W. J. Spillman (Nat. Stockman and Farmer, 34 (1910), Nos. 37, pp. 960, 961; 38, p. 991).—The article outlines the principles in farm bookkeeping and illustrates a system of double-entry bookkeeping that can be kept by any farmer.

Farm bookkeeping (Rd. Agr. and Fisheries [London], Leaflet 210, pp. 8).—A simple system of farm bookkeeping requiring few books or different places of entry is discussed.

The agricultural valuer's assistant, T. Bright (London, 1910, 5. ed., pp. XII+308).—This publication is intended to assist the agricultural tenant-right valuer to better prepare himself for discharging the various duties of his profession. The tables are compiled and arranged in such a way as to show at a glance various calculations relating to agricultural products and labor. The author discusses and explains the various items to be considered and the methods used in determining the valuation of landed estates; gives tables showing the method of calculating the value of manures and feed stuffs from analyses; sundry costs and values; measurement of stacks of hay, corn, and straw; compensation for land taken for public purposes; and miscellaneous items as to agricultural products.

The appendix gives a digest of the Agricultural Holdings Act, 1908, with a full text and commentary thereon.

Our farmers and our future, R. H. Forbes (Univ. Ariz. Rec., 2 (1910), No. 2, pp. 23).—This is an address delivered October 21, 1909, in a course of public lectures at the University of Arizona, in which it is shown that the cultivated lands in Arizona have increased by reason of irrigation from 5,000 or 10,000 acres to about 230,000 acres within the last 55 years, and that further development of the country is dependent upon the storage of flood waters, the development of underground supplies, the more effective application of water in agricultural operations, and the direct utilization of rainfall.

Agricultural statistics (Bicen. Rpt. Bur. Labor Statis., Colo., 12 (1909-10), pp. 279-291).—This chapter shows there are between 2,750,000 and 3,000,000 acres under irrigation in Colorado, and gives tables showing the production in 1909 and 1910 per acre of the 5 principal grain crops, including the acreage, bushels, price, and total value of each, and the amount of fruit and sugar production in 1910.

Primary production, J. B. Trivett (Statis. Reg. X. S. Wales, 1910, pt. 7, pp. 577-719).—A statistical register of New South Wales showing the area, production, and average yield of the principal crops, together with comparative tables giving the average of the various crops and the average value per acre for the several districts and counties from 1900 to 1909, inclusive.

European agricultural returns (Nyasal. Govt. Gaz., 1909, May 31, Supp., pp. 3).—A statistical report showing the acreage and estimated tonnage for 1908-9 upon the following agricultural crops in the Nyasaland Protectorate: Cotton, coffee, tobacco, fiber, chillies, tea, wheat, oats, and rice.
AGRICULTURAL EDUCATION.

Agricultural education: Educational periodicals, B. M. Davis (El. School Teacher, 11 (1910), No. 1, pp. 15-23).—In this number the author discusses in particular the influence of Barnard's Journal of Education on the development of agricultural education, and in a more general way 3 groups of educational periodicals: (1) Those devoted to general problems in education and having general circulation, in which the attention given to agricultural education is said to be much less than would seem to be warranted in view of the great public interest in the subject; (2) special periodicals, including those devoted to some single phase of education, as, for example, orthography, penmanship, manual training, etc., among which 2 are mentioned as devoting considerable attention to agricultural education, one in the field of secondary agriculture, and the other in the field of elementary agriculture; and (3) local journals of education, several of which are said to have exerted a strong influence for the promotion of agricultural education. A bibliography of some of the leading articles appearing in educational periodicals is given.

Agricultural education: Periodical literature, B. M. Davis (El. School Teacher, 11 (1910), No. 2, pp. 78-89).—The importance of popular periodicals is recognized by the author, but he says that "on the whole, agricultural periodicals have maintained too conservative an attitude toward agricultural education, both as to colleges and elementary and secondary schools." As indicating the nature of the work done by popular periodicals a review is given of some of the leading articles on the general subject of agricultural education that appeared in the periodicals of this country in 1903, near the beginning of the active promotion of elementary and secondary agricultural education. Several other articles are also reviewed, and all of these are referred to definitely in a bibliography.

Agricultural education: State organizations for agricultural and farmers' institutes, B. M. Davis (El. School Teacher, 11 (1910), No. 3, pp. 136-145).—In this contribution to agricultural education the author discusses the influence of state departments of agriculture, state fairs, agricultural contests held under the direction of the state offices of agriculture, and state farmers' institutes. A bibliography of the subject is appended.

Agricultural education: Agricultural societies, B. M. Davis (El. School Teacher, 11 (1911), No. 5, pp. 266-271).—In this article four periods are recognized in the relation of agricultural societies to the development of agricultural education, viz: (1) The period of beginnings, from 1785-1850; (2) the period of agricultural fairs, from 1850-1870; (3) the period of great organizations, from 1870-1892; and (4) the period of adjustment, from 1892 to the present time. Much credit is given to the early agricultural societies in Pennsylvania, New York, and Michigan for the agitation which led to the establishment of agricultural colleges, and the influence of such societies is recognized in later years as having a bearing on the progress of these institutions, as well as a more or less independent value in promoting agricultural education in the fields not covered by the colleges of agriculture.

Briefly summarized these recommendations are (1) state aid as at present provided for industrial schools to any town or group of towns constituting a district for the establishment and maintenance of an independent agricultural school; (2) the establishment of agricultural departments in existing high schools with state aid and with rigid definition and enforcement of vocational standards; and (3) to meet the needs of Worcester by the foregoing provisions.

The report contains discussions in detail of the following topics: Does Massachusetts farming warrant the establishment of a system of agricultural schools? The system of agricultural schools recommended for Massachusetts; cooperation between school and home farm necessary to an effective system of agricultural schools for Massachusetts; the part-time project method necessary to an effective system of agricultural schools for Massachusetts; the problem of securing competent instructors for a system of agricultural schools in Massachusetts; agricultural departments in public high schools the principal present need in Massachusetts agricultural education; possible locations for agricultural schools or departments; recommendations with regard to agricultural education for Worcester; agriculture as a phase of liberal education in the high schools of Massachusetts; and agriculture as a phase of liberal education in the elementary schools of Massachusetts.

An appendix contains a proposed law embodying recommendations of the board.

Report of the Michigan State Commission on Industrial and Agricultural Education (Rpt. Mich. State Com. on Indus. and Agr. Ed., 1910, pp. 95).—This commission was appointed by the Governor of Michigan in the summer of 1909, and organized by appointing subcommittees on industrial and trade schools, child labor conditions, agricultural education, and rural education. This pamphlet contains the definitions, conclusions, and recommendations of the whole committee, reports of the respective subcommittees, a paper on The Present Condition of Industrial Education in Germany, by E. C. Warriner, and three appendixes containing (a) statistics on agricultural high schools in Michigan and Minnesota, rural districts in Michigan, county agricultural schools in Michigan and Wisconsin, and other data; (b) typical courses of study in agricultural high schools, public high schools in Maine, Iowa, Illinois, and Nebraska, and county agricultural schools in Michigan and Wisconsin, industrial courses in a number of cities, and suggested agricultural and industrial courses for Michigan; and (c) authorities, including a list of schools visited and a bibliography.

Among the recommendations of the commission are (1) the provision of at least one high school with a four-year course in each township; (2) the introduction as soon as possible of agriculture, manual training, and home economics into all high schools; (3) certification of all teachers of agricultural and industrial subjects; (4) state supervision of all agricultural and industrial courses, and (5) state aid for schools introducing high school courses in agriculture and home economics, as follows: (a) The total not to exceed $30,000 for the first year, $50,000 for the second year, and $100,000 for any subsequent year, (b) an equal division of the funds between agriculture and home economics on the one hand, and industrial courses on the other, and (c) schools certified for aid in agriculture and home economics to receive $500 for the first teacher employed, and $250 for each other teacher employed, and no school to receive more than $1,000 in all.

Some observations on high school agriculture, L. Anderson (Nature-Study Rev., 7 (1911), No. 3, pp. 77-79).—The author discusses schools that came under his observation during an extended trip for the purpose of visiting special agricultural schools and public high schools having agricultural departments. He
deals particularly with public high schools in Virginia, New York, Minnesota, Michigan, and California.

Results of boys' demonstration work in corn clubs in 1910, S. A. Knapp and O. B. Martin (U. S. Dept. Agr., Bur. Plant Indus. Doc. 677, pp. 7, figs. 3).—The origin of boys' corn club work in connection with the farmers' cooperative demonstration work is traced back to 1906, and a brief review of the development of the movement since 1900 is given.

The number of boys engaged in this work in 1910 was 46,225, and the highest yield on 1 acre was 228½ bu. grown at a cost of 43 cts. a bushel by Jerry Moore at Winona, S. C. It is stated that in Lincoln County, Miss., 48 boys averaged 92 bu. per acre; in Clarendon County, S. C., 142 boys averaged 62 bu.; in Appomattox County, Va., 17 boys averaged 83.7 bu.; and 100 of the boys in the South made an average of 133.7 bushels per acre.

MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1910 (U. S. Dept. Agr. Rpts. 1910, pp. 953).—This consists of the report of the Secretary and heads of Bureaus. The various reports are also issued as separates. A portion of the report of the Secretary, comprising a discussion of the prices of farm products to the producer and consumer, is abstracted on page 90 of this issue.

Report of the Secretary of Agriculture, 1910. James Wilson (U. S. Dept. Agr. Rpt. 93, pp. 98).—This report, which is reprinted in abridged form from the publication noted above, contains a review of the work of this Department for the fiscal year ended June 30, 1910.

Twenty-second Annual Report of Georgia Station, 1909 (Georgia Sta. Rpt. 1909, pp. 87-96).—This contains the organization list, reports by the president of the board of directors and by the director of the station on its work during the year, and a financial statement for the fiscal year ended June 30, 1909.

Twenty-third Annual Report of Michigan Station, 1910 (Michigan Sta. Rpt. 1910, pp. 137-549, figs. 289).—This contains reports of the director and heads of departments on the work of the station during the year, the experimental features of which are abstracted elsewhere in this issue, reprints of Bulletins 256-261, Special Bulletins 51-53, Technical Bulletins 2-4, and Circulars 6-9, previously noted, and a financial statement for the fiscal year ended June 30, 1910.

Report of the director, 1910, H. L. Russell (Wisconsin Sta. Bul. 203, pp. 63, figs. 12).—This contains the organization list, a report of the work of the station during the year, especially those phases dealing with administration, research, publications, and extension work, brief summaries of the publications of the year, lists of donations and exchanges, and a financial statement for the fiscal year ended June 30, 1910.

Monthly Bulletin of the Department Library, February and March, 1911 (U. S. Dept. Agr., Library Mo. Bul., 2 (1911), Nos. 2, pp. 33-58; 3, pp. 61-90).—These numbers contain data for February and March, 1911, respectively, as to the accessions to the Library of this Department and the additions to the list of periodicals currently received.

Experiment Station Work, LXII (U. S. Dept. Agr., Farmers' Bul. 435, pp. 24, figs. 6).—This number contains articles on the following subjects: Water required for crops on rich and poor soils, burning lime on the farm, growing tomatoes for the canning factory, lime-sulphur as a fungicide, market classes and grades of meat, keeping poultry free from lice, and Neufchatel cheese
Idaho University and Station.—Appropriations have been made of $6,000 for a two-story and basement stock and dairy barn, with a concrete silo and milk room adjoining, a $3,000 stock-judging pavilion of mission style to accommodate 120 students, $13,000 for the purchase of additional land, and $20,000 for extension work in Southern Idaho. A dry-farming substation is to be established in the southeastern part of the State for work in cooperation with this Department.

Illinois University and Station.—A total appropriation of $3,600,000 was made to the university for the ensuing biennium, of which $952,500 is for the college of agriculture and experiment station. Provision was also made for levying a one-mill tax during the next 2 years upon the assessed valuation of the State. The revenues thus derived will constitute a fund from which the next legislature may make detailed appropriations to the institution.

Among the several items granted are $210,400 per annum for maintenance of the college and station, $168,000 per annum for special investigations by the station in live stock, farm crops, soils, orchards, floriculture, and dairying, $19,000 for the purchase of improved live stock, $3,500 for additional equipment for the farm mechanics laboratory, and $153,000 for new buildings. This includes $34,000 for additions to existing buildings and the erection of several small structures; $80,000 towards a live-stock building and large pavilion to cost eventually $100,000; $39,000 for green houses; and $20,000 for the purchase of 40 acres of land for the poultry plant and additional field experiments.

The legislation provides for the inauguration of work in soil biology, poultry, and forestry, and for additional work in veterinary science, landscape gardening, floriculture, animal nutrition, and agricultural extension.

Fred L. Charles, assistant professor of agricultural education since 1900, died at Urbana May 6, at the age of 38 years. Prof. Charles was a graduate of Northwestern University, from which institution he also received in 1895 the M. S. degree. Subsequently he specialized further in biology and zoology at the University of Chicago and elsewhere. His early work in teaching was in public and secondary schools, but in 1890 he became professor of biology at the Northern Illinois State Normal School, where he remained for 10 years, giving special attention to the methods of teaching nature study in the public schools. His work at the University of Illinois had been largely in the formulation of plans for the introduction of agriculture into the elementary schools of the State, in which field his work was largely of a pioneer nature. At the time of his death he was also editor of Nature Study Review.

Louisiana Stations.—George Chaquelin, formerly assistant chemist at the Sugar Station, has been appointed assistant director of the Sugar Station, vice H. P. Agee, whose resignation has been previously noted.

C. C. Moreland and C. B. Sherrouse, 1911 graduates of the university, have been appointed assistants in plant pathology in connection with the researches under the Adams Act.
NOTES.

Plans and specifications for a new residence at the North Louisiana Station for the assistant director have been prepared and bids for construction are being received. The former residence was destroyed by fire in January.

Minnesota University.—The State legislature has granted $1,283,900 to the university, $399,700 for the school of agriculture, $89,200 for the Crookston school of agriculture, $2,100 for the Crookston substation, $15,500 for the Grand Rapids substation, $199,750 for the Morris agricultural school, $65,000 for a substation at Duluth, and $85,000 for one at Waseca.

The extension division received an increase from $25,000 per annum to $40,000, and the farmers’ institutes an increase from $18,000 to $23,000. In addition $2,000 was allotted for prizes in the State boys’ and girls’ industrial contest under the auspices of the extension division. A horse barn was authorized to cost $5,000 and a hog barn to cost $1,500.

New Jersey Stations.—Provision has been made by recent acts of the legislature for carrying on experiments in poultry production and floriculture. Buildings are to be erected for these purposes in the near future.

The State board of agriculture has been authorized to appoint a plant pathologist for the study of chestnut blight of forest trees. He is to cooperate in this work with the State forester. The State entomologist has been authorized to investigate problems pertaining to the foul brood of bees.

North Carolina College.—A commission of five is to be appointed from the State legislature to meet with the State board of agriculture and the trustees of the college for an investigation of the advisability of consolidating these institutions or to arrange for additional cooperation between them.

An appropriation of $30,000 was granted for an animal husbandry building. There was also provided $80,000 annually for maintenance, and $15,000 annually during 1911 and 1912 for permanent improvements.

North Dakota College and Station.—State appropriations aggregating nearly $200,000 have been made for the ensuing biennium. Of this about $112,000 is for the maintenance of the college, $13,000 for that of the school of forestry, $25,000 for that of the 5 substations, and $24,000 for that of the 23 demonstration farms, together with $15,550 for additional buildings and other equipment at the substations.

South Dakota College and Station.—The appropriations by the legislature for maintenance for the ensuing biennium aggregate $131,000. Among the items are $4,000 each for the substations at Eureka and Cottonwood, $6,000 for the Highmore substation, $1,000 for a new substation to be located in Fall River County for dry farming tests, $1,000 for seed testing, $2,000 for the distribution of hardy alfalfa, and $2,000 for popular bulletins.

The grant for farmers’ institutes was increased from $10,000 to $26,000. Several new buildings were authorized, including a $100,000 agricultural and administration building, $4,000 for an addition to the creamery building, and $6,500 for buildings at the substation. The establishment of a demonstration farm at Vivian in Lyman County was authorized under certain conditions.

Tennessee University and Station.—The thirty-eighth annual session of the East Tennessee Farmers’ Convention, of which the director of the station is secretary, was held at the university May 16-18. The attendance was about 1,500. There were ten speakers from the university and station and a number from other stations and this Department. An inspection of the station farm constituted an important feature of the meeting.

The sum of $6,000 was appropriated from the treasury of the convention to assist in the erection of an assembly hall and live-stock pavilion on the station farm to cost $12,000. Considerable sums have been pledged by individuals and the balance will be supplied subsequently from funds of the convention.
Vermont University and Station.—Dr. Guy P. Benton, president of Miami University, Oxford, Ohio, has been chosen president of the University. G. C. Cunningham, a 1900 graduate of the Ontario Agricultural College and a post-graduate student in plant pathology and bacteriology at the University of Wisconsin, has been appointed assistant plant pathologist in the station and has entered upon his duties. Clarence Carpenter, a 1911 graduate of the university, has been appointed assistant bacteriologist, and P. M. Lombard assistant horticulturist.

A better-farming-special train was recently sent out in northern Vermont. One car was devoted to forestry and horticulture, one to farm crops and fertilizers, one to dairying, and a fourth to agricultural education and home economics.

West Virginia University.—D. W. Working has resigned as superintendent of agricultural extension to accept a position in the Office of Farm Management of this Department.

Agricultural College in British Columbia.—An act of the recent provincial legislature sets aside 170 acres at Point Grey, a Vancouver suburb, for the site of a provincial university, and makes a grant of 2,000,000 acres of public lands for its maintenance. Plans are being formulated for the erection of over 30 buildings. One important group is to be provided for a college of agriculture, with accompanying schools of forestry, domestic science, and veterinary science. A central farm in connection with the college is proposed, as well as several branch farms in the Province.

Agricultural Instruction in Porto Rico.—Instruction in agriculture is now offered by the University of Porto Rico, at Rio Piedras, and by the department of education in 6 of the 41 supervisory districts, the latter being work of an elementary nature. In each of these districts there is a special teacher of agriculture who gives instruction in the graded schools and superintends the work of the rural teachers in that subject. Gardens are maintained in connection with the work and in some instances the sale of the products, such as sugar cane, pineapples, citrus fruits, tobacco, and vegetables, has placed quite a fund at the disposal of the teacher for the purchase of fertilizers, implements, etc. Courses in manual training and domestic science are maintained in the high school and university courses, and courses in sewing to a limited extent in the graded schools.

A New Association of Agricultural Educators.—A conference on secondary agricultural education was held in Chicago April 10. It was attended by representatives of the departments of agricultural education of Minnesota, Wisconsin, Illinois, Indiana, Michigan, and Ohio, the principals of the 3 agricultural schools in Minnesota, and the specialists in agricultural education of the New York State Department of Education, the United States Bureau of Education, and this Office.

Among the topics discussed at the conference was the number of units feasible to be taught in high schools having special teachers of agriculture, in consolidated rural or graded schools, and in one-room rural schools. As regards the number of units in the four-year high school course it was voted as the consensus of opinion that, if a special teacher of agriculture is provided, four years of agriculture are feasible and desirable. There was also considerable discussion of the scope of rural school nature study and of ways and means of securing up-to-date information on agricultural education. A resolution was adopted requesting the cooperation of the United States Commissioner of Education and the Director of the Office of Experiment Stations in the collecting of such material.
It was voted to form a permanent organization and K. L. Hatch, of Wisconsin, was elected president, and W. H. French, of Michigan, secretary-treasurer, with power to decide upon a name for the association and arrange for subsequent meetings. The president has suggested the name of The American Association for the Advancement of Agricultural Teaching.

Elementary Agricultural Education in South Carolina.—The seventh annual report of the commissioner of agriculture, commerce, and industries of South Carolina includes a report of a special commission appointed by the general assembly of South Carolina to investigate and report upon the advisability of establishing and maintaining agricultural schools and branch experiment stations in the State.

In this report the commission enumerates the various forces at work in South Carolina to improve agricultural methods, and recommends that instead of establishing separate agricultural high schools the State create a commission on agricultural education, to consist of the state superintendent of education, the commissioner of agriculture, one member of the board of trustees of Clemson College, the director of the agricultural department of the college, the professor of secondary education of the University of South Carolina, and the professors of elementary agriculture and elementary education at Winthrop College. This commission would be charged with making and executing general plans for agricultural education in South Carolina, including the appointment of a director of agricultural education, who should be an officer of the state department of education, and may be a professor in Clemson College. The duties of this officer, as outlined by the commission, would be to coordinate and harmonize all of the forces now directed toward agricultural education in the schools of the State, prepare and distribute among the schools special bulletins outlining definite work to be done, give specific directions to teachers of agriculture, distribute seeds to schools, and perform such other duties as the commission may direct.

The commission also recommends that special courses designed to prepare teachers of agriculture for the elementary and secondary schools be offered by Clemson College, Winthrop College, and the state university, and that teachers who have thus prepared themselves to teach agriculture and who have received the proper credentials for such work should receive from the state appropriation a small compensation in addition to the salary paid by the district trustees.

Under this plan the work to be done by the director of agricultural education and the commission on agricultural education is to be supported by state appropriations.

Industrial Education in Maine.—The report of the Maine state superintendent of public schools for 1910 contains the report of the committee on investigation of industrial education appointed by the state superintendent in accordance with a resolve passed at the 1909 session of the legislature. Their report deals with industrial (including agricultural) education in European countries and in America, a synopsis of typical state laws regarding industrial education, the present status of industrial education in Maine, and the needs of Maine industries, with recommendations with reference to the preparation of special teachers, the elementary schools, agricultural education, secondary schools, continuation courses, separate trade schools, and the control of industrial courses.

The committee recommends among other things the introduction of hand work, including drawing, manual training, and domestic science, into all grades of elementary schools; greater emphasis on the local geography, history, and industries, and the direction of all school work toward the experiences of the child; school and home gardens; courses for training teachers in agriculture,
manual training, and domestic science; encouragement by the State of courses in agriculture, manual training, and domestic science, in public high schools and academies; evening continuation courses in manufacturing and industrial centers; and permissive legislation for the establishment of separate trade schools.

New Journals.—*The American Review of Tropical Agriculture* is being published monthly as the official organ of the Rubber Planters' Association of Mexico. The late Pehr Olsson-Seffer, Ph. D., has been its editor, with headquarters at Mexico City, and the board of associate editors has included Prof. C. F. Baker, of Pomona College, the late J. B. Carruthers, of Trinidad, E. B. Copeland, Ph. D., of Manila, R. M. Olsson-Seffer, of Leland Stanford Jr. University, F. E. Lloyd, of the Alabama College and Station, and others. Its object as announced is to disseminate throughout North and South America the latest experiences of science and practice in tropical agriculture in all the various branches. One of the recent numbers contains an account by the editor of rubber and coffee growing in the Orient and in Mexico; an article on The Growing of Guayule in Relation to the Soil, by J. E. Kirkwood; articles on The Flow of Latex in Rubber Plants and Agricultural Possibilities in Tropical Mexico, by the editor; Causes of Destruction of Agricultural Land in Mexico, by R. I. Olsson-Seffer; a bibliography of rubber, reviews of current literature, book reviews, and miscellaneous notes.

*The Agricultural Journal of the Companhia de Moçambique* is published quarterly in English and Portuguese, being edited by the Director of Agriculture assisted by the staff of the Agricultural Department of Mozambique. It is designed especially as a medium of communication between the department and the farmers and planters of the country, to whom it is distributed free of charge. The initial number contains a variety of material, including an article on maize cultivation at M'Zimbiti experimental station, notes on the coconut beetle, official notices, statistical data, etc.

The student body of the College of Agriculture, Los Banos, P. I., is issuing *The Philippine Agriculturist and Forester*. It appears monthly during the college year and the initial numbers contain descriptions of the work of the college, general articles designed to improve the agriculture of the islands, abstracts of agricultural literature, etc.

The Nebraska State Horticultural Society has established *Nebraska Horticulture* as its official organ. The initial numbers contain a variety of brief articles including several by members of the staff of the Nebraska University and Station.

Miscellaneous.—The Cuban government offers a prize of $30,000 to the individual who discovers the cause, cure, or means of control of the coconut disease that is destroying many of the trees in that country.

Dr Pehr Olsson-Seffer, formerly instructor in botany in Leland Stanford Jr. University, and recently director of the Tezonapa Botanical Laboratory and botanist of the Mexican Government, was recently killed in Mexico, at the age of 38 years.

Horace G. Deming of the University of Wisconsin has been appointed associate professor of agriculture in the Philippine College of Agriculture.

Notes 194

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Chemical-technical analysis, Lunge, Berl et al 106
Method for estimating nitric acid, Angelucci 106
A simple method for the estimation of potassium, Grete 106
The estimation of potassium as potassium platinic chlorid, Fresenius 107
Estimation of phosphoric acid by direct weighing, von Lorenz 107
The titrannetric estimation of phosphorus in small amounts, Bowser 107
Determination of the basicity of Thomas slag powder, Michel 107
Biochemical handbook, edited by Abderhalden 107
Action of metallic salts of gold group on saccharification of starch, Gerber 107
A glucosid from Tephrosia purpurea, Clarke, jr., and Banerjee 107
Determining the enzymatic activity of nuclease by the optical method, Pigliin. 108
Micropoliarization, Fischer 108
Detection of nitrogen in organic substances, Ellis 108
A new method for determining pentosans, Flohil 108
Food codex of the Netherlands, IV, Vandevelde 108
Serodiagnostic methods, Thöni 108
Fat estimation in meat, Diesselhorst 108
Utilizing the anaphylaxis reaction for detecting meat adulteration, Miesmer 108
Biological method for detecting horse fat in other fats, Wittels and Welwart 108
Determining coco fat in lard with aid of ethyl-ester number, Hanuš and Thian 108

98334°—No. 2—11—1
Determining the dry matter content of potatoes, Björn-Andersen .......................... 109
The chemistry of bee honey, Hasterlik ................................................................. 109
Honey and its analysis, Muttedt ............................................................................... 109
Analysis of honey, Curtel ......................................................................................... 109
Determination of gum in gum syrups, Bellier ......................................................... 109
The shell and germ content of cocoa products, Huss .............................................. 109
Estimation of citric acid in citrates and lemon juices, Spica ...................................... 109
A new method for the analysis of wine, Friderich ..................................................... 109
Detection of saccharose in wine, Schaffer and Philippi ............................................. 110
The chemical examination of hops, Kunz ................................................................. 110
A new method for examining pepper, Arragon ......................................................... 110
The detection of olive husks in pepper, Bondil ......................................................... 110
Estimation of reducing sugars in vinegars, Hasbrouck .............................................. 110
The bacterial deterioration of sugars, Owen ............................................................... 110
Extraction of grains and cattle foods for determination of sugars, Bryan et al. ........ 110
Estimation of total solids in milk by the use of formulas, Shaw and Eckles ............ 112
The accuracy with which proteins can be estimated in milk, Richmond .................. 113
The polarimetric estimation of milk sugar, Richmond ............................................... 113
Rapid estimation of coconut oil in admixture with butter fat, Cassal and Gerrans ...... 113
Method for coloring fat in Gerber acido-butyrometric method, Hoyberg .................. 113
Interpretation of the analytical results for milk adulterations, Farina .................................. 113
Influence of potassium bichromate on the results of milk analyses, Garnier .......... 113
The volatile oils, Gillemese and Hoffman ............................................................... 113
The methiod content of Hungarian peppermines, Cap................................. 113
Determining oil of sesame in arachis oils, Kreis ...................................................... 114
[Palm oil; its utilization as an edible fat], Fickendeys ............................................. 114
Purification of insoluble fatty acids, Holland ......................................................... 114
Detection of albumin in animal urine with tablet reagents, Beyer ............................. 114
On the estimation of urea, Taylor ............................................................................. 114
Identification of methyl alcohol in ethyl alcohol, Engelhardt and Jones ................. 114
Analyses of mixed paints, Ladd and Johnson ............................................................ 115
Manufacture of cereal vinegars, Hoffmann .............................................................. 115
Alcohol formation during sauerkraut fermentation, Wehmer .................................... 115
Potato alcohol in Russia, Grout .............................................................................. 115
Information for distillers and yeast manufacturers, Kusserow .................................. 115
Preparation of caramel, Hazewinkel ........................................................................ 115
Report of the experiment station at Augustenbarg, 1909, Mach .................................. 115
Agricultural-chemical laboratories in Germany, Holland, and Belgium, Lugner .......... 115

METEOROLOGY—WATER.

Meteorological observations, Stockdale ................................................................. 115
A new sand evaporimeter, Demolom and Brown ...................................................... 115
Dissolved matter contained in rain water at Lincoln, New Zealand, Gray ............... 115
Snow limits and climate, Paschinger ...................................................................... 116
The cycle of water ................................................................................................. 116
Indispensable conditions for good hygiene of wells, Lomry ...................................... 116
Mercury vapor lamps and action of ultraviolet rays, Perkin ....................................... 116

SOILS—FERTILIZERS.

[Papers on soils and soil investigations] ...................................................................... 116
The volumetric constitution of soils .................................................................... 117
Tanks for soil investigations at the Florida Station, Blair and Collison .................. 117
Influence of shade on the evaporation of water from the soil, von Seelhorst .......... 118
Pyritic moor soils as a foundation for drainage structures, Fendler and Frank ....... 118
On the plasticity of clay soils, Van Bemmelen ....................................................... 118
Soil organic matter for biochemical investigation, Schreiner and Shorey .......... 118
Cholesterol bodies in soils: Phytosterol, Schreiner, and Shorey .............................. 118
Oxidation in soil, Sullivan and Reid ...................................................................... 118
The Norfolk fine sandy loam, Bonsteel ................................................................. 119
The Norfolk fine sand, Bonsteel ............................................................................ 119
[County geological surveys in Iowa], Arey, Macbride, Stooye, and Shimek .......... 119
Soil observations in Istria: Red soils (terra rossa), Wilhelm Grai zu Leiningen .... 119
Some results of a flying soil survey, Aston ............................................................... 119
Influence of the soil on the composition of some plants, Dormaar ......................... 120
Value of root residues as nitrogen collectors and green manure, Hotter et al. ....... 120
## CONTENTS

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>On the penetration of fertilizers into the soil, Demolon and Brouet</td>
</tr>

| The potato eelworm, Doten and Frandsen. | 145 |
| The potato eelworm, Doten and Frandsen, trans. by Trost | 146 |
| On the presence of *Tilletia horrida* in rice flour, Filler | 145 |
| A new myxomycete on sugar beets, Nemec | 145 |
| Root tumors of sugar beet | 145 |
| Experiments on the control of Phytophthora on tobacco, Jensen | 145 |
| Injury caused by the apple powdery mildew, Volck | 145 |
| The occurrence of apple blotch in Ohio, Gloyer | 146 |
| A summary of various spraying experiments, Watkins | 146 |
| The use of dilute lime-sulphur for the control of apple diseases, Scott | 147 |
| The cherry in Lower Burgundy.—V, Diseases of cherries, Larne | 147 |
| Crown swelling disease of peach, Norton | 147 |
| Observations on the California vine disease, Butler | 147 |
| A new enemy of grapes, Hahn | 148 |
| On a bacteriosis of the tomato, Pavarino | 148 |
| Some diseases of the banana | 148 |
| A bacterial disease of bananas and plantains, Rorer | 148 |
| *Sphaeropsis tumefaciens* n. sp., the cause of the lime and orange knot, Hedges | 149 |
| A new disease of mulberries, Babik | 149 |
| On *Melanconis modonia*, a parasite of the chestnut in Brittany, Ducomet | 149 |
| The black canker of the chestnut, Briosi and Farnetti | 149 |
| The parasitism of *Diaporthe parasitica* on the chestnut, Pantanelli | 149 |
| The chestnut bark disease, Ranc | 149 |
| Hevea disease in Ceylon (*Phytophthora faberi*), Ridley | 149 |

**Economic Zoology—Entomology.**

| General biology, Needham | 150 |
| A history of British mammals, Barrett-Hamilton | 150 |
| South African moles, Dreyer | 150 |
| A history of birds, Pycraft | 150 |
| The birds of Australia, Mathews | 150 |
| Economic ornithology in recent entomological publications, M[cAtee] | 150 |
| Notes on the fruit-eating habits of the sage thrasher, Kennedy | 150 |
| A comparative study of methods of examining feces for parasites, Hall | 150 |
| [A note on the viability of nematode eggs and larvae], Ransom | 151 |
| How to control the boll weevil and the bollworm, Hayhurst | 151 |
| Animal enemies of the beet, Schlelein | 151 |
| Some insects affecting the tobacco crop, Mackie | 151 |
| [Insect enemies of the plum and olive], Noel | 151 |
| Notes on some Thysanoptera, Bagnall | 151 |
| Spraying experiments against grape leafflower in Lake Erie Valley, Johnson | 152 |
| Some synonymy and other notes on Aphidiinae, Gahan | 153 |
| The use of potassium permanganate against the woolly aphis, Ahrens | 153 |
| Compounding miscible oils for controlling white fly, Yothers and Crossman | 153 |
| A new scale insect, Anstead | 153 |
| Recent work with fungus parasites of scale insects | 154 |
| On the probable viviparity in some pierid butterflies, Kusnezov | 154 |
| An outbreak of destructive caterpillars in Batangas rice fields, Mackie | 154 |
| Notes on the geometrid *Gypsochroa steltula*, Russell | 154 |
| Life history of codling moth and its control on pears in California, Foster | 154 |
| Notes on the life history of the larch case bearer, Herrick | 157 |
| Summary of food habits of American gall midges, Felt | 157 |
| Two rare leaf enemies of fruit trees, Korff | 157 |
| A new chironomid miner, Willen | 157 |
| Some facts indicating that malaria may be spread through other agencies than the anopheline mosquitoes, Chico | 157 |
| Researches on the development of the ox warble (*Hypoderma torridum*), Vaney | 157 |
| Biological studies on the glossiness of central Dahomey, Roubaud | 158 |
| Experiments on transmission of bacteria by flies, Orton and Dodd | 158 |
| Role of insects as agents in propagation of ergot of the Gramineae, Mercer | 158 |
| Concerning the trypasome in *Myrurus vitellos*, Lavaren and Peittet | 158 |
| The rat flea as the intermediate host of a rat tapeworm, Nicoll | 158 |
| A catalogue of the Coleoptera | 158 |
| Further biological notes on *Leptinotarsa decemlineata*, Girault and Zetek | 159 |
| The elm-leaf beetle, Herrick | 159 |
Budworms in corn (Diabrotica 12-punctata), Turner.............. 159
The application of cold to the destruction of tobacco beetles, Pook..... 159
The roll weevil advance in Alabama, Hinds........................ 159
The alfalfa weevil (Sphenophorus maidis), Kelly..................... 160
Disseased bees and comb infected with a protozoal parasite, Pantham and Porter... 161
A new prototrophic parasite of the larva of Anthrenus muscorum, Tran... 161
Note on a parasite of the black scale of the olive, Ruby................ 161
Transmission of spotted fever by other than Montana and Idaho ticks, Mayer.... 161
Transmission of spotted fever by the tick in nature, Mayer.............. 161
A contribution to the study of Trypanosoma hippicum, Laveran.......... 161

[Miscellaneous food topics], Foust................................... 166
Biennial report of the state dairy and food commissioner, 1909-10, Hansen.... 166
Laws of Wyoming providing for pure food, drugs, drink, and illuminating oils... 166
How to plan meals, Jacobs............................................ 166
Food economy.............................................................. 167
Food and efficiency of the rural population, Kaup........................ 167
The relationship of food to physical development, McCoy................ 167
The perils of low protein diets, Broadhurst................................ 167
A contribution to the theory of protein metabolism, Schrage............... 167
A comparative study of the nitrogenous extracts of veal and beef, Skworzow... 167
Nitrogen partition in feces, Labbé..................................... 167
The synthesis of fatty acids in the body, Forges.......................... 168
Synthesis of fat in body cells and fat in food, Abderhalden and Brahms........ 168
The digestibility of connective tissue, Baumstark and Cohnheim............. 168
Role of electrolytes in saccharification of starch by amylases, Lisboa........ 168
On the presence of allantoin in certain foods, Ackroyd.................... 168
The utilization of the mineral salts of milk by nursing infants, Marre........ 168
Experiments on the metabolism of phosphorus, Gregersen.................. 168
Digestive processes, Bardier.......................................... 169
The use of biological methods in studies of the digestive tract, Citron........ 169
The catalase content of tissues and organs after prolonged fasting, Hawk..... 169
Metabolism and energy transformations during rest, Benedict and Carpenter.. 169
Old age deferred, Lorand.............................................. 170
CONTENTS.

Page.
Practical dietetics with reference to diet in disease, Pattee.......................... 170
Pattee's handbag diet book, Pattee.................................................. 170
Use of rice bran in the prevention and cure of beriberi, Bréquaud and Denier.... 170

ANIMAL PRODUCTION.

The genotype conception of heredity, Johannsen........................................ 170
Inheritance of acquired adaptations, Kummerer........................................... 171
Dominance and the modification of behavior in alternative inheritance, Tower... 171
Some effects of temperature upon growing mice, Summer................................ 171
Further investigations on changes in species, Woltereck.............................. 171
Organic response, Macdougall.............................................................. 171
Recent work on the inheritance of acquired characters, Alexander.................. 172
Recent literature on Lamarck and Lamarckism, May.................................... 172
A sketch of Mendel's life and work, Scourfield....................................... 172
The nucleus and heredity, Blackman...................................................... 172
Application of pure lines to inheritance and sexual dimorphism, Morgan......... 172
On the effect of a differential fertility on degeneracy, Pearson..................... 172
Fertility of hybrids between Bison americanus and B. europaus, Iwanoff......... 172
On the determination of the chief correlations between collaterals in the case of
a simple Mendelian population mating at random, Snow................................ 172
Computing correlation where symmetrical tables are commonly used, Jennings... 173
An abac for determining the probable errors of correlation coefficients, Heron... 173
Report of the first International Congress of Breeding and Feeding................. 173
Reports of the first International Congress of Breeding and Feeding............... 173
The new respiration apparatus at the Berlin Agricultural College, Zuntz........ 173
Chemical analyses of licensed commercial feeding stuffs, 1910, Woll................ 173
Licensed commercial feeding stuffs, 1911, Woll........................................ 173
The lecithin content of meadow grass, Becker.......................................... 173
A contribution to the effect of plasmase, Greve........................................ 173
Fattening cattle on blue grass pasture, Munnford...................................... 174
The influence of bedding on gains in steers, Tacke.................................... 174
Raising calves on skim milk, Eckles and White......................................... 175
Cattle breeding in the district about Tabora, Wölfel................................. 175
The woolen and worsted industries, Clapham............................................. 175
The influence of the Steppes climate and vegetation on caracul fleece, Adametz... 175
Concerning the zebu and animal breeding in Germany, Augustin....................... 175
Observations with camels, Meiisser....................................................... 175
Farmers' handbook on swine, Short....................................................... 175
Breeds of hogs, crops, and other data, Dalrymple, Dodson, and McClendon........ 175
Spanish peanuts, dwarf Essex rape, and cowpeas for swine, Flint................... 175
Feeding experiments with dried beer yeast, von Czadeck................................ 175
Hog houses, Warren................................................................................. 175
Fattening turkeys.................................................................................... 176

DAIRY FARMING—DAIRYING.

Dairying, Fascetti...................................................................................... 176
Trial of soy-bean cake, Mackintosh and Goodwin........................................ 176

North Dakota Station:
- Paint Bul. 5, Apr., 1911 .......... 115

Note.—The price of Experiment Station Record is $1 per volume, and two volumes are issued annually. It may be purchased from the Superintendent of Documents, Washington, D. C., to whom all remittances should be made. The publications of the State experiment stations are distributed from the stations and not from the Department.
One by one those who took part in the beginnings of agricultural experimentation in this country pass away. Sturtevant, Johnson, Goessmann, Cook, Atwater—these belong to the first generation of workers in agriculture. The men of their time have largely given place to a second generation, now in the full vigor of middle life, who with the greater opportunity which the times afford, in experience, funds, and popular appreciation, are throwing their whole lives into the advancement of agriculture as an industry and as a condition under which men live.

Dr. E. B. Voorhees, of New Jersey, was a type of this present generation of leaders. In a sense he was a link between the old and the new régime, for he was trained under the pioneers, and his most notable work was done since the experiment station movement became a national one. He represented in a characteristic way the vigor and aggressiveness of the new generation in organizing and propagating experiment station work, and in making its results felt by the farmers. He shared generously in the confidence and appreciation which have come of such effort, and in the demand for leadership which this agricultural awakening has brought. He was a product of his times, the embodiment of a new idea.

His life was not a long one, as the world measures time, but it was crowded full. In its fifty-five years there was more of life and accomplishment than in the three score and ten of many another man.

Edward Burnett Voorhees was born at Minebrook, Somerset County, New Jersey, on June 22, 1856. He died June 6, 1911.

He was graduated from Rutgers College in 1881 with the degree of bachelor of arts, and in 1900 he received the honorary degree of doctor of science from the University of Vermont. The year following his graduation he served as assistant to the professor of chemistry at Wesleyan University, Prof. W. O. Atwater; and in 1882 he returned to New Jersey as assistant chemist in the experiment station. This station, the third or fourth in seniority of American stations, had been established two years previously, and was under the directorship of Dr. George H. Cook. Doctor Voorhees continued as assistant chemist until 1888, when he was made chemist. Following the death
of Doctor Cook he was appointed professor of agriculture in Rutgers College, in 1890, a position which he held for twenty years, developing agricultural instruction in that institution almost from the beginning, his efforts being crowned with a good measure of success and leading the State to the establishment of the short courses in agriculture.

In 1893 Doctor Voorhees was made director of the New Jersey State Station, and three years later the directorship of the College Station was combined with this. Under his hand the inspection work of the stations was put upon a high plane of efficiency and usefulness, and the research and experimental work were developed in accordance with definite plans and an intelligent understanding of the needs of the State. He inspired and assisted his coworkers in the station, providing for them opportunity and suitable conditions for their studies, and securing recognition for what they accomplished. He was director in a true sense, maintaining sympathetic and helpful relations with the men of his staff, and a vital connection with the principal lines of investigation.

As an independent investigator he was versatile, resourceful, clear in aim and purpose, and quick to see the practical applications of his experiments. Indeed, these were conceived for the most part with the primary object of throwing light on practical every-day questions, for however deep his interest in the science of agriculture, the art and the problems of the men engaged in it were never lost to his sight.

He carried on an elaborate series of studies on nitrogenous fertilizers, the first ten years' results of which were summarized in Bulletin No. 221 of the New Jersey Stations. A review of this work was also presented at the International Congress of Applied Chemistry in London in 1909.

More recently, in collaboration with Doctor Lipman, he had given special attention to investigations in soil chemistry and bacteriology. The New Jersey Station was a pioneer in the latter branch, and although its example has been followed by other stations it has remained a leader in that line. The department sprang from Doctor Voorhees's initiative and his ability to perceive the important bearings of the subject. Its establishment and development on so high a plane is one of his most conspicuous accomplishments. In 1902 he was awarded the Nichols medal by the New York Section of the American Chemical Society, for the best paper embodying the results of original chemical research submitted during the year. The contribution on which this award was made was based on work conducted in the new department, and was entitled Studies in Denitrification.

Doctor Voorhees was a pioneer in teaching the farmers the practice of home mixing of fertilizers, to economize cost and secure suitable
mixtures for different purposes. He was an ardent champion of honest goods, and waged an aggressive campaign against the incorporation of materials which his experiments showed to be inert and of little agricultural value. He called sharp attention to the difference which may exist between commercial and agricultural values, especially in case of different forms of nitrogenous manures. His reports on the fertilizer inspection were full of vigor and life, and contained deductions and suggestions which were interesting and helpful to the practical man in drawing conclusions from the tables of figures.

With remarkable energy and enthusiasm Doctor Voorhees encouraged and promoted the diversification of agriculture in his State, the introduction of new crops, and the establishment of new branches of farming. The system of soilings crops for dairy cattle which he worked out and demonstrated at the station farm was an example in intensive farming under which the purchase of expensive grains was greatly reduced. The home growing of protein was a popular theme with him. The successful establishment of alfalfa in New Jersey is a direct result of his experiment and teaching. It is estimated that a thousand acres were seeded to this crop last fall. He gave special study to the waste or poor soils of the State and their utilization for profitable farming; and at one time he devoted considerable attention to the use of irrigation as an adjunct in the humid regions.

These things illustrate the versatility and breadth of interest of the man, and show how quick he was to perceive a need and to seek means of meeting it. It was this breadth and quick perception, his clearness of purpose and energy in setting work in motion, that constituted one of his strongest attributes as a station director.

Doctor Voorhees was identified with many scientific societies and organizations, in whose work he shared. For many years he took an active part in the study of methods of analysis conducted by the Association of Official Agricultural Chemists, and he was president of that organization in 1893–94. For seven years (1897–1904) he was secretary-treasurer of the Association of American Agricultural Colleges and Experiment Stations, and was president of the association in 1904–5.

His connection with the State Board of Agriculture was especially noteworthy. He served as vice-president of that board from 1893–1901, and was its president from that date to the time of his death, giving a large amount of attention to its interests and activities. He was president of the Board of Directors of the New Jersey Weather Bureau in 1893, president of the New Jersey Microscopical Society 1905–6, and a leader on the State Conservation Commission.
“In the rapid movement of agricultural science in an unknown and then but lowly place, to its present lofty place among the sciences of the schools and of the national life, he thus bore his worthy and far from inconspicuous part."

The broad educational influence of an agricultural teacher is not to be measured merely by the hours spent in the class room or the number of students which come directly under him. His contributions to the advancement of knowledge, his influence in the promotion of worthy educational ideals, and his dissemination of useful knowledge among mankind, must receive due weight of consideration.

This is notably true in the case of Doctor Voorhees. He rendered a far broader service to higher education in agriculture than the teaching of the students who attended his classes. One of the fundamental things in the development of the American system of agricultural education has been the provision of textbooks and manuals for different grades of instruction. As a thoroughly trained scientist, devoting himself especially to studies in plant nutrition and the theory and practice of manures and fertilizers, Doctor Voorhees brought together the results of his studies and experience as a teacher in what is the standard American text-book on fertilizers, which has passed through eleven editions. This has been used by a large number of students in the college courses in agriculture. He was also the author of an important manual on forage crops, and contributed to the Encyclopedia of American Agriculture standard articles on fertilizers, green manures, and cover crops.

In a lower range of educational effort his book entitled First Principles of Agriculture has had an important part in helping on the now widespread movement for secondary education in agriculture. To this class would also belong the Book of Corn, in the preparation of which he was a collaborator.

As a teacher of men actually engaged in agriculture throughout New Jersey and in many other States, Doctor Voorhees was among the foremost workers in the cause of what has come to be called extension in agriculture. He had a rare combination of scientific accuracy with sound practical judgment, and a method of presentation of the subject to practical minds which was very attractive and convincing. He was trusted by practical men as a wise and safe leader, and there were many evidences of the high appreciation in which his aid was held.

Doctor Demarest has well said of him: “A supreme characteristic was his devotion to work, his incessantness in the affairs of his vocation. His interests were many and wide; his chosen calling brought him into manifold relations, many communities of men, many places
of responsibility, many circumstances of demand. Any of them as an exclusive work might have commanded his energy of all the days and years; each of them commanded its place, and its degree of his care and effort, and the record of any week or month showed his versatile and unremitting zeal. The world's work was his work and he cast in all his living. He did the full day's work without measure. . . .

"His was a rare enthusiasm. He burned with devotion to the cause to which he gave his life. An ardent belief in the resources and opportunities with which he had to do urged him on, inspired his far-reaching effort, and became the prophecy of great accomplish-ments. He was ambitious and confident and courageous. . . .

"Out from the college and station center his work, and his personality pervaded the State and even played their part in the life and progress of the nation. In the most material way the resources of the State were in far degree developed by that which came forth from his brain and hand. . . . It was his custom to go ceaselessly about the State, and his visits to communities and clubs were a vigorous campaign of scientific truth. Thus not only were great and continuous material results achieved, but as well a singular personal influence was created and wrought widely for good.

"This singular hold upon the people and service of them was recognized in many appointments by the State itself and by organizations within its bounds. Such official places were not only the consequence of his unusual activities and acceptance, but the vantage point for still more effective work for the public good. His counsel was always sought and respected; he it was who largely shaped policies, formulated plans, and guided the movements of such enterprises.

"It is difficult to measure the reach of such a life; but it is safe to say that there are few men in the life of the State who have been more warmly regarded, more surely trusted, and more plainly fol-

lowed than he."
RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Chemical-technical analysis, G. Lunge, E. Berl et al. (Chemisch-technische Untersuchungsmethoden. Berlin, 1910, vol. 2, 6. ed., rev. and enl., pp. XVI—869, figs. 138; Sup. pp. 8).—This is the second volume of the work previously noted (E. S. R., 22, p. 508), and deals with physical, mechanical, and chemical methods for the analysis of cyanogen compounds, clays, glass, cement, water, sewage, soils, air, iron and other metals, calcium carbide, and acetylene.

Method for estimating nitric acid, O. Angelucci (Abs. in Chem. Ztg., 34 (1910), No. 112, p. 294).—In this method from 0.2 to 0.5 gm. of the substance is mixed with 3 gm. of fused and powdered lead chromate. The mixture is then put in a porcelain boat and inserted in a combustion tube which is open at both ends. On one side of the tube are placed successively a 30 cm. layer of metallic copper, copper oxid (15 to 20 cm.), and a copper netting (5 to 6 cm.), and it is then connected with an azotometer (nitrometer). Carbon dioxide is passed through the apparatus with a capillary tube, and when the air has been displaced the combustion tube is heated to from 400 to 500° C. The nitrogen oxides formed are reduced by the metallic copper, and the pure nitrogen is collected and measured in the azotometer.

A simple method for the estimation of potassium, A. Grete (Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gesundheitsv., 1 (1910), No. 5, pp. 295—297; abs. in Chem. Ztg., 34 (1910), No. 117, p. 1040).—This is a simplification of the Finke—Neubauer method (E. S. R., 12, p. 714), and consists of boiling 20 gm. of the air-dry substance in a liter bottle until solution has taken place. Sodium hydroxid and ammonia are then added until all the precipitable substances are thrown down and the reaction is slightly alkaline toward phenolphthalein. The mixture is cooled and filled up to the mark with water, and the precipitate allowed to settle.

A measured quantity of the clear fluid is evaporated to dryness in a beaker (resistant glass), and if necessary with the addition of a little sodium hydrate to remove the remaining ammonia. If amides are present these are broken down with a little sodium hypochlorite or chlorin water, and where much organic matter is in the mixture this is oxidized in a platinum dish with a little sulphuric acid. The residue is acidified with hydrochloric acid, treated with an excess of platinitic chlorid, and evaporated to a small bulk. In order to wash the potassium platinitic chlorid thoroughly and remove the sulphates and chlorids which may be present, the residue is taken up with a little water, 100 cc. of 96 per cent alcohol added, and shaken. The precipitate formed is collected in a Gooch crucible by the aid of suction, washed several times, dissolved in water, and magnesium chips and sulphuric acid added to reduce the platinum. The mixture is then filtered through a Neubauer-Gooch crucible
(E. S. R., 21, p. 710), and the filtrate treated in the usual manner for determining potash.

The estimation of potassium as potassium platinic chlorid, H. Freesius (Österr. Chem. Ztg., 13 (1910), No. 24, pp. 394, 395).—The author sought to determine the influence which various salts exert upon the results of the estimation of potassium as potassium platinic chlorid in a solution of potassium chlorid. The work shows that where much calcium chlorid is present with potassium chlorid and sodium chlorid, and is not previously removed, the results for potassium are high. The same was found to be the case for potassium in admixture with sodium, magnesium, and barium chlorids.

The tests made to determine the proper strength of alcohol for this work showed that 70 per cent alcohol gave low results and 85 per cent high results, while 95 per cent alcohol gave good results for the potassium oxid but with evidences of a possibility of reducing the sodium chlorid to the oxide state. A concentration of 90 per cent alcohol is deemed the best.

Estimation of phosphoric acid by direct weighing of the ammonium phospho-molybdate, N. von Lorenz (Österr. Chem. Ztg., 14 (1911), No. 1, pp. 1-5).—This article deals with the question of the priority of this method (E. S. R., 13, p. 14) and criticizes Jörgensen's findings with a similar method (E. S. R., 19, p. 506). The method is again described in detail and its application for slags, soils, and ashes is discussed.

The titrametric estimation of phosphorus in small amounts, L. T. Bowser (Amer. Chem. Jour., 45 (1911), No. 3, pp. 239-237).—The method, briefly stated, is as follows: Use a convenient volume of solution, but see that when ready for precipitation it is not less than 20 cc. For less than 0.8 mg. P₂O₅ use 1 cc. molybdate solution, for more 1.5 cc. and 0.5 gm. ammonium nitrate, precipitate at 55° C., keep for 1 hour at that temperature, let stand for 2 hours, filter and wash. Titrate with a standard hydroxid solution not stronger than 0.02 N.

Determination of the basicity of Thomas slag powder, R. Michel (Chem. Ztg., 34 (1910), No. 93, p. 830; abs. in Chem. Abs., 5 (1911), No. 1, p. 51).—The author proposes heating 1 gm. of the powder with about 15 cc. of 20 per cent ammonium nitrate solution in a 200-cc. round-bottom flask. The ammonia is then driven off by means of air which has been previously passed through sulphuric acid, and which is allowed to bubble through the mixture for three-quarters of an hour. The ammonia is caught in an excess of tenth-normal acid solution. A blank experiment conducted without slag powder liberated no ammonia.

Biochemical handbook, edited by E. Abderhalden (Biochemisches Handlexikon, Berlin, 1911, vol. 5, pp. VI+671).—This volume treats of the alkaloids, animal poisons, products of internal secretions, antigens, and ferments.

Action of the metallic salts of the gold group upon the saccharification of starch by the amylolytic ferments, C. Gerber (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 4, pp. 139-145).—Cadmium, chlorid, zinc chlorid and sulphate, silver nitrate, and mercuric chlorid were studied in regard to their effect upon the action of starch ferments.

A glucosid from Tephrosia purpurea, G. Clarke, Jr. and S. C. Banerjee (Jour. Chem. Soc. [London], 97 (1910), No. 575, pp. 1833-1837; abs. in Zentral. Biochem. u. Biophys., 11 (1910), No. 1, p. 8).—From an alcoholic solution or extract of this legume, the authors isolated a glucosid which on hydrolysis yields quercetin, rhamnose, and glucose, and possesses the formula C₇H₅O₃+3H₂O.

9834°.—No. 2—11—2
Determining the enzymatic activity of nuclease by the optical method, G. Pighini (Ztschr. Physiol. Chem., 70 (1910), No. 2-3, pp. 85-93, figs. 14).—The author at first utilized the various chemical methods for this purpose, but the results obtained were not entirely satisfactory. He contrived a method based upon an observation made by Jones, who found that nucleic acid rotates the plane of polarized light to the right. The method gave good results.

Micropolarization, E. Fischer (Betr. Deut. Chem. Gesell., 34 (1911), No. 1, pp. 129-132, figs. 2).—A description of the method and apparatus used for the polarization of small amounts of substance.

Detection of nitrogen in organic substances, H. R. Ellis (Chem. News, 102 (1910), No. 2655, p. 187; abs. in Chem. Abs., 5 (1911), No. 1, p. 75).—The organic body is heated on porcelain or platinum in a test tube with metallic magnesium and either sodium or potassium carbonate. Compounds which contain nitrogen and carbon yield cyanogen, while those containing halogens and sulphur form halogen salts and sulphids.

A new method for determining pentosans by the aid of the copper reduction method, J. T. Flohil (Chem. Weekbl., 7 (1910), No. 51, pp. 1057-1063).—The method is based on the determination of the reducing power of the furfurol in the distillate, which is obtained in the usual manner.

Food codex of the Netherlands.—IV. General methods for the analysis of various foods of vegetable origin, A. J. J. Van de Velde (Rev. Gén. Chem., 13 (1910), Nos. 19, pp. 307-313; 21, pp. 325-330).—Among the topics treated in this part are the qualitative and quantitative reagents and methods for determining water, ash and ash constituents, fat, protein, and carbohydrates in foods.

Fat estimation in meat, G. Diesselhorst (Arch. Physiol. [Pflüger], 134 (1910), No. 9-10, pp. 496-500).—A comparative study was made between the Lehmann ball mill method and Dormeyer’s pepsin hydrochloric acid digestion method (E. S. R., 7, p. 919) for estimating fat. The results show that Dormeyer’s method extracts other bodies in addition to fat, whereas the results obtained by the Lehmann method gives constants which are typical for fat.

Utilizing the anaphylaxis reaction for detecting meat adulteration, H. Miessner (Centbl. Bakt. [etc.], I. Abt., Orig., 56 (1910), No. 2, pp. 163-177).—It appears from the results that when a guinea pig is treated with heterologous antigens it becomes anaphylactic to both of the antigens, but that the test with one of the two antigens has no influence on the other antigen.

It is also possible to detect antigens (proteins) which have been boiled. An interval of from 40 to 50 days from the last injection is the best time to test for the presence of raw and boiled meats. The methods used are discussed.

Biological method for detecting the presence of horse fat in other animal fats, Wittels and Welwart (Seifensieder Ztg., 37 (1910), p. 914; abs. in Chem. Zentrbl., 1910, II, No. 16, p. 1249; Analyst, 35 (1910), No. 4, pp. 537).—The test depends upon the differentiation of the proteins contained in the various animal fats by the biological precipitin reaction (E. S. R., 22, p. 680).

Determining coco fat in lard with the aid of the ethyl-ester number, J. Hanuš and J. Thian (Ztschr. Untersuch. Nahrw. u. Genussmft., 20 (1910), No. 12, pp. 745-749).—The authors once more (E. S. R., 18, p. 811) point out the value of the ethyl-ester figure for detecting the adulteration of lard with foreign fats. The method is again described.

b Arch. Physiol. [Pflüger], 97 (1903), No. 11-22, pp. 606-633, figs. 4.
Determining the dry matter content of potatoes, H. Björn-Andersen (Tidsskr. Landbr. Plantavl., 17 (1910), No. 3, pp. 519-528).—This is a critical study of the methods of Heideprim, Holde-leiss, Adesser, Maaecker, and A. J. Hansen for obtaining the percentage of dry matter in potatoes from the specific gravity, and supplemented by the author’s work, which included determinations of both the dry matter and specific gravity of a large number of samples of 15 different varieties of potatoes. The conclusion is reached that an error of at least 1 per cent is frequently made by calculating the dry matter content from the specific gravity of the potatoes, and that where greater accuracy is called for, direct determinations of dry matter should be made.

The chemistry of bee honey, A. Hasterlik (Leipzig, Bielen Ztg., 26 (1911), Nos. 2, pp. 27-28; 3, pp. 30-31).—This is a review of the progress made in the chemistry of bee honey during 1910.

Honey and its analysis, F. Muttelet (Ann. Falsif., 3 (1910), No. 26, pp. 503-513).—A general discussion of honey standards and the adulteration of honeys, particularly those honeys obtained by feeding bees with sugar and giving Fiche’s reaction (E. S. R., 20, pp. 612, 909, 1009). The author makes it a practice to conduct his honey examinations organoleptically, microscopically, polariscopically, and chemically.

Analysis of honey, G. Curtel (Ann. Falsif., 3 (1910), No. 26, pp. 497-502).—A description of the usual methods for estimating and standards for protein, invert sugar, moisture total solids, acidity, ash, and chlorids, as well as of Land’s method for albumin (E. S. R., 21, p. 393), Fiche’s reaction, Ley’s reaction, the polarization before and after inversion, and tests for glucose and dextrin.

Determination of gum in gum sirups. Bellier (Ann. Falsif., 3 (1910), No. 26, pp. 528, 529).—This method is based on the principle of precipitating the gum with alcohol in the presence of such salts as barium chlorid, magnesium chlorid, and calcium chlorid. Preference is given to the calcium salt.

The shell and germ content of cocoa products, H. Huss (Ztschr. Untersuch. Nahr. u. Genussmittel, 21 (1911), No. 2, pp. 94-101).—After reporting the results of factory tests in regard to freeing cocoa products from the shell and germ, the author propounds the question as to what would be a fair limit for these substances. He lays particular stress on the elimination of such terms as traces, small amounts, etc., and sets the limit for cocoa mass at 2 per cent, for chocolate at 1 per cent, and for cocoa at 3 per cent.

A microscopic method is also described for obtaining approximate quantitative figures for the shell and germ content of these products. This is based on the fact that the mucus cells of the shell and the germ tissue do not take a stain composed of (1) Congo red 1 gm. and water 100 gm.; (2) brilliant blue 1 gm., glycerin 20 gm., and water 80 gm.; and (3) Sudan III 0.1 gm., glycerin 50 gm., and alcohol (95 per cent) 50 gm. The samples which are to be examined are compared with other authentic samples of known shell and germ content. Milk fat and other normal substances which may be present are stained by these reagents.

Estimation of citric acid in citrates and lemon juices, M. Spica (Chem. Ztg., 34 (1910), No. 128, pp. 1141, 1142, figs. 2; abs. in Analyst, 35 (1910), No. 417, p. 519).—The method is based upon the precipitation of citric acid as calcium citrate, heating this with sulphuric acid, and measuring the carbon dioxide which is driven off. The carbon dioxide has a direct relation to the amount of citric acid present.

A new method for the analysis of wine, Friderich (Monit. Sci., 4, scr., 24 (1910), 11, No. 827, pp. 705-710, figs. 7).—After discussing the physical-chemical
principles underlying the method, the author describes the method in detail, as previously noted (E. S. R., 19, pp. 913, 1110; 20, p. 708).

Detection of saccharose in wine, F. SCHARF and E. PHILIPPI (Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gesundheitsbl., 1 (1910), No. 5, pp. 294, 295; abs. in Chem. Ztg., 34 (1910), No. 117, p. 1049).—Numerous sugared, artificial, and authentic natural wines and some grape juices prepared by the authors were examined according to Rothenfusser's method (E. S. R., 22, p. 10).

The results show that the blue coloration obtained with hydrochloric acid and diphenylamin is probably the result of the formation of oxymethyl furfurrol from the sugars and these reagents. Orcin, according to the authors, is an even more sensitive reagent.

The chemical examination of hops, L. KUNZ (Pure Products, 7 (1911), No. 1, pp. 39-44).—The author describes a quick method for estimating the bitter substances in hops, which has for its purpose the control of the amount of hops to be added to beers in order to produce a uniform bitter for every brew.

A new method for examining pepper, C. ARAAG (Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gesundheitsbl., 1 (1910), No. 5, pp. 271-273; abs. in Chem. Ztg., 34 (1910), No. 117, p. 1049).—Pepper, according to the author, possesses a very constant iodin number. He states that when 2 gm. of pepper are treated in the same manner as fat when estimating the iodin value according to Hübli, a value is obtained which, when calculated to 100 gm., is in the neighborhood of 17. If starch is present, this figure is reduced.

The detection of olive husks in pepper, F. FONDIL (Ann. Falsif., 4 (1911), No. 27, p. 36).—The test is based on the coloration of the stone cells by a fresh solution of paraphenylenediamin and a few drops of acetic acid. The test can also be used for detecting sawdust in flour, bread, etc.

Estimation of reducing sugars in vinegars, F. F. HABSBROUCK (Pure Products, 7 (1911), No. 2, pp. 80, 81).—A discussion in regard to inaccuracies in determining the reducing sugars in vinegars and a description of a good procedure for this purpose is given.

According to the author the deterioration is caused by the group of bacteria which comprises the potato group of bacilli. The spores of the species isolated causing the deterioration of sugars were found to be very resistant to heat and capable of surviving the various processes of sugar manufacture. The actual destruction of sucrose is due to an extracellular gum- (levan) forming enzyme, which the author terms “levanase.” It produces the changes according to the following equation: \( C_6H_{12}O_6 = C_6H_{12}O_6 + C_6H_{10}O_5 \), and acts best in a slightly alkaline medium.

The author also points out that the formation and presence “of levan in sugars introduces an error in both the single polarization and Clerget methods of determination of sucrose. This error causes a decrease in the single polarization of 0.6 Ventzke for every 1 per cent of levan, and an increase of 0.67 Ventzke for Clerget in the presence of 1 per cent of gum. Owing to this factor of error, a sugar in which gum formation has taken place would show an increase in sucrose by the Clerget method of determination.”

A bibliography of 30 titles is appended.

Extraction of grains and cattle foods for the determination of sugars: A comparison of the alcohol and the sodium carbonate digestions, A. H. BRYAN, A. GIVEN, and M. N. STRAUGHEN (U. S. Dept. Agr., Bur. Chem. Circ. 71, pp. 14).—This is a description of a quantitative extraction method for determining the sugar contained in grains, cattle feeds, and vegetable materials, which has
already been mentioned (E. S. R., 19, p. 840) and used in work previously described (E. S. R., 22, p. 258).

In detail it is as follows: "Place 12 gm. of material in a 300 cc. graduated flask, add 150 cc. of 50 per cent alcohol by volume (carefully neutralized), mix thoroughly, and boil on a steam bath for 1 hour, using a small funnel in the neck of the flask to condense the vapor. Then cool. If desired, allow it to stand overnight. Make up to volume with 95 per cent alcohol (neutral in reaction), mix thoroughly, allow to settle, transfer 200 cc. to a beaker with a pipette, and evaporate on steam bath to a volume of from 20 to 30 cc. The presence of a trace of alcohol is not harmful. Do not evaporate the solution to dryness. (By evaporating the 200 cc. portion in a short-necked, balloon-shaped distilling flask, connected with a condenser, 75 to 80 per cent of alcohol can be recovered before the material in the flask foams violently. The short neck—1 in.—of these flasks makes it possible to remove the residue easily. The 100 cc. remaining in the digestion flask may be strained through a cotton bag and the alcohol recovered from the liquid as just described. This is easily accomplished and results in a marked saving when a large number of samples are run.) Transfer the contents of the beaker or flask, as the case may be, to a 100 cc. graduated flask, washing thoroughly with water. Add enough of a saturated solution of neutral lead acetate to produce a flocculent precipitate and allow to stand 15 minutes.

"At this point the solution may safely stand overnight if desired. Make up to the mark with distilled water and pass through a folded filter, carefully saving all of the filtrate, to which add enough anhydrous sodium carbonate to precipitate all the lead, allow to stand 15 minutes, and pour onto an ashless filter. Over 75 cc. of filtrate should be obtained. Test the filtrate for lead with a small quantity of dry sodium carbonate, and if any precipitation occurs add more anhydrous sodium carbonate and refilter. Use 25 cc. of this clear filtrate together with 25 cc. of water for the determination of reducing sugars by the method of Munson and Walker. In a 100 cc. graduated flask, place 50 cc. of the same filtrate, add a small piece of litmus paper, and neutralize with acetic acid; then add 5 cc. of concentrated hydrochloric acid and let stand overnight for inversion. (Standing 48 hours does not apparently affect the results.) Then pour the inverted solution into a 100 cc. beaker and neutralize with anhydrous sodium carbonate; return it to the 100 cc. flask and make up to the mark. Filter, if necessary, and use 50 cc. for the determination of total sugars as invert by the method of Munson and Walker.

"The amount of cuprous oxide or copper obtained in either the reducing or the total sugar determination represents the sugar contained in 2 gm. of the material. Therefore the weights of the invert sugar when divided by 2 and multiplied by 100 give the respective percentages of sugar as invert. Subtract the percentage of reducing sugars before inversion from the percentage of total sugar after inversion, both calculated as invert, and the difference multiplied by 0.95 gives the percentage of sucrose. Since the insoluble material of the grain or cattle feed occupies some space in the flask as originally made up, it is necessary to correct for this volume. Results of a large number of determinations on various materials have shown the average volume of 12 gm. of material to be 9 cc.; therefore the correction factor for 12 gm. in 300 cc. is 0.97, and the percentage figures for reducing sugar and sucrose are to be multiplied by this factor to obtain the true amounts."

\[a\] If the material is acid in reaction, it would be well to add from 1 to 3 gm. of precipitated calcium carbonate to neutralize the acidity.
A comparative study of this method and the sodium carbonate aqueous extraction method was made, utilizing various kinds of material. It showed that the alcohol method gave lower but satisfactory and comparable results, and it made no difference whether the extract was analyzed immediately or after standing for some time.

The authors point out that in order to obtain true and concordant results with the sodium carbonate method careful attention must be given to some of the details of manipulation, as, for instance, "after neutralizing the sodium carbonate by clarifying with alum or lead, the work must be carried on with dispatch as the enzymes again become active; the acidity of the sample must be determined and the quantity of sodium carbonate thereby regulated, or the accuracy of the results will probably be affected; normal lead acetate should be used instead of alum for clarification under most circumstances, otherwise an error is introduced."

The authors express the opinion that the alcohol method is to be given the preference for general sugar work, but that where a long series of comparable results are necessary the sodium carbonate aqueous method may sometimes be used to advantage.

This work forms a part of investigations concerning milk which are in progress in cooperation with the Missouri Station. It was carried out for the purpose of testing the accuracy of various formulas in common use (Babcock's, Richmond's, and Fleischmann's) for determining the total solids in milk, and to determine whether an improvement could not be made in the way of obtaining an easy, accurate method for determining the specific gravity of milk for the use of such men as usually have charge of official testing.

With the above objects in view, the authors compared the percentages of total solids calculated by means of formulas and of total solids found by the gravimetric method. They further compared the formula whose results came closest to the gravimetric figures, under very exacting conditions, and finally sought to modify the existing, or devise a new, lactometer for determining the specific gravity accurately. The fat and total solids in this work were determined by the Babcock asbestos method, while the specific gravity was determined with the Westphal balance at 15° C.

From the work the authors conclude:

"For purposes where exact percentages of total solids are demanded, the use of any formula will not fulfill the requirements.

"Of the formulas in general use, that known as the Babcock (revised) formula gave results closest to those obtained gravimetrically. In 430 composite samples analyzed for total solids 256, or nearly 60 per cent, when calculated with this formula agreed within 0.25 per cent of the figures obtained gravimetrically, and 389, or over 90 per cent, agreed within 0.50 per cent. In another test with 84 samples of milk obtained from four individual cows under official testing conditions, determinations made on each milking showed that the total solids calculated by the formula in 53 cases, or 63 per cent of the total, agreed within 0.25 per cent of the gravimetrically determined figures; and in 78 cases, or 93 per cent of the total, they agreed within 0.50 per cent."

"Neither individuality nor breed in the cows seemed to exert any notable influence upon the application of the formulas.

"The Babcock formula may be safely used with normal milk where only comparatively close approximations are required. It must be left to the decision of those in need of such figures as to whether or not the formula will fulfill their particular requirement."
"The lactometers in common use for determining specific gravity of milk are not sufficiently sensitive to be used in connection with the Babcock fat test for estimating total solids in milk by formula. A modification of the Quevenne lactometer was, however, devised which was found to yield results quite as accurate as those obtained with the Westphal balance and at the same time so constructed that it may be used successfully by those unskilled in the use of chemical apparatus."

The degree of accuracy with which proteins can be estimated in milk by aldehyde titration, H. D. Richmond (Analyst, 36 (1911), No. 418, pp. 9-12).—The aldehyde figure of milk (E. S. R., 22, p. 309) was found to agree well with the results obtained by the Kjeldahl method when using the factor 6.38 for the latter. The maximum errors of a single determination were +0.2 and —0.13. An abnormal milk containing much albumin had a limit of error of 0.5 per cent.

The polarimetric estimation of milk sugar, H. D. Richmond (Analyst, 35 (1910), No. 417, pp. 516, 517).—Acid mercuric nitrate, according to the author, does not in every case precipitate all the proteins from milk or from a solution of milk products. He, therefore, utilizes a double precipitation method, which "is to prepare the solution for the polarization of milk sugar with acid mercuric nitrate as usual, and to add to this 5 per cent of phosphotungstic acid and 5 per cent of 1:1 sulphuric acid. After filtration, the solution is polarized and the reading multiplied by 1.1."

The results obtained by the new method were very much higher.

A rapid process for the estimation of coconut oil in admixture with butter fat, N. C. Cassal and B. H. Gerrans (Chem. News, 102 (1910), No. 2655, pp. 190, 191).—The author describes a method with which it is possible to increase markedly the difference between the titration figures for the insoluble fatty acids from coconut oil and those for the insoluble fatty acids from butter. The process is simple and requires only about 2½ hours.

A method for coloring the fat precipitated in the Gerber acidobutyrometric method, H. M. Hoyberg (Ztschr. Vliesch u. Milchhyg., 21 (1910), No. 2, pp. 36, 37).—In order to determine whether the fat has been completely precipitated, the author recommends coloring it with Sudan III. by adding it to the amyl alcohol in the form of a 2 per cent alcoholic solution.

Interpretation of the analytical results for milk adulterations, A. Farines (Indus. Lait. [Paris], 36 (1911), No. 2, pp. 17-21).—After discussing the various factors which influence the composition of milk, the author describes the mathematical and other methods for detecting the addition of water, the removal of cream, and the simultaneous removal of cream and addition of water.

The influence of potassium bichromate on the results of milk analyses, L. Garnier (Jour. Pharm. et Chim., 7, ser., 3 (1911), No. 2, pp. 55-59).—The author determined the effect of adding bichromate to milk (1:1,000) upon the ultimate results obtained on analysis. It seems that the addition of this substance increases the acidity, refraction, and cryoscopic constants, but diminishes the lactose content.

The volatile oils, E. Gildemeister and F. Hoffmann (Die Ätherischen Öle. Leipzig, 1910, vol. 1, 2. ed., pp. VII+697, pls. 2, figs. 75).—This is the first volume of the second edition of this well-known work, which was prepared under the direction of Schimmel and Company of Leipzig. The second edition has been edited by Dr. E. Gildemeister.

The menthol content of Hungarian peppermint oil, K. Ikr (Kisérlet. Közlem., 13 (1910), No. 4, pp. 376-391).—The following results were obtained: Ester content from 6.93 to 16.26 per cent, menthol ester 5.46 to 12.82 per cent, free menthol 42.81% to 59.90 per cent, total menthol 55.19 to 55.38 per cent, and
menthon 7.38 to 13.21 per cent. The results are compared with peppermint oils from various countries.

Determining oil of sesame in arachis oils, H. Kreis (Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gesundheitsamt., I (1910), No. 5, pp. 293, 294; abs. in Chem. Ztg., 34 (1910), No. 117, p. 1040).—The author lays particular stress upon the value of estimating the sesamin content of arachis oils. As the result of examining microscopically 20 such oils, which contained quantities varying from 1 to 5 per cent of pure arachis oils, using 150 cc. of oil at one time and with the aid of Bömer's reaction (acetic anhydrid and concentrated sulphuric acid), he was able to establish a fairly good quantitative method for sesame oil in these oils.

[Palm oil; its utilization as an edible fat], F. Pickendey (Tropenpflanzer, 11 (1910), No. 11, pp. 566-570; abs. in Jour. Soc. Chem. Indus., 29 (1910), No. 22, p. 1319).—As the production of palm oil is now commercially feasible, the author points out the following criteria which must be taken into consideration in producing a good product. They are (1) the use of absolutely ripe and fresh fruit, (2) the necessity of destroying the lipolytic enzym, and (3) the rapid treatment of the fruit to avoid undue contamination with microorganisms.

Purification of insoluble fatty acids, E. B. Holland (Abs. in Science, u. ser., 33 (1911), No. 831/2, pp. 334, 335).—"As the author found it impossible to purchase insoluble fatty acids of a satisfactory quality," it became necessary to undertake a study of various methods for their purification. The methods that seemed the best adapted for the purpose were (a) distillation of the fatty acids in vacuo, (b) crystallization from alcohol, and (c) distillation of the ethyl esters in vacuo, and all were given extended trial.

"It was found that while saturated fatty acids may be purified by distillation of either the acids or their ethyl esters, the latter method is less hazardous and much easier to manipulate, although more steps are required. Crystallization is a finishing rather than an initial process of purification."

Detection of albumin in animal urine with tablet reagents, P. E. Beyer (Über den Nachweis von Eiweiss im Tierharn mit Merck's Tabletten, Hühng. Diss., Univ. Bern, 1909, pp. 39, tables 4).—The author tested Merck's tablet reagents (Esbach's test, picric and citric acids, Riegler's β-naphthalene sulphonic acid, and Merck's "A and B," which consists of (A) citric acid and (B) potassium ferricyanid) in regard to their relative value for detecting albumin in human, dog, horse, and bovine urines, and concludes that Riegler's test furnishes the most accurate and constant results. He also tested the value of Merck's Esbach tablets for detecting creatinin in urine, and found that these served the purpose very well.

A bibliography of 75 titles is appended.

Identification of methyl alcohol in ethyl alcohol, H. Engelhardt and H. W. Jones (Merck's Rpt., 20 (1911), No. 1, pp. 10-12).—The experiments were confined principally to those methods in which the oxidation is carried out in an acid medium with potassium permanganate, potassium bichromate, or ammonium persulphate. The results show that Hinkel's method is the most satisfactory, and that with it less than 0.5 per cent of methyl alcohol in ethyl alcohol can be detected.

A Analyst, 33 (1908), No. 392, pp. 417-419.
Analyses of mixed paints, E. F. Ladd and Alma K. Johnson (North Dakota
Sta. Point Bul., 5, pp. 57-71).—This is a statement of the composition of com-
mercial paints of various brands, which in some instances were obtained on the
open market, and in others direct from the manufacturer. Analyses of the
pigment and the vehicle are given, and the results are discussed.

Manufacture of cereal vinegars, W. Hoffmann (Deut. Essigindus., 14 (1916),
Nos. 50, pp. 369, 370; 51, pp. 377, 378).—A description of the processes involved
in the manufacture of cereal vinegars, with particular reference to malt vinegar.

Alcohol formation during sauerkraut fermentation, C. Wehmer (Centbl.
Bakt., [etc.], 2, Abt., Ref., 28 (1916). No. 4-5, pp. 97, 98; abs. in Chem. Ztg., 3)
(1910), No. 142, p. 585).—It is observed that during the fermentation of cab-
bage a certain amount of alcohol is produced with the lactic acid.

Potato alcohol in Russia, J. H. Groul (Daily Cons. and Trade Rpts. [U. S.],
14 (1911), No. 22, p. 37/8).—A report in regard to the progress made in the pro-
duction of potato alcohol in Russia.

Information for distillers and yeast manufacturers, R. Kusserow (Pure
Products, 6 (1910), No. 11, pp. 619-622).—This article deals with the im-
portance of the proper solution of the nitrogenous substances in mashing and
its influence on fermentation, and further, the effect of the addition of sugar
or a fermented wort.

Preparation of caramel, J. J. Hazewinkel (Meded. Proefabt. Java-Suiker-
indus., 1910, No. 49, pp. 497-524).—Tests in regard to the preparation of car-
amel from sugar (molasses, etc.) with the aid of lime are reported and discussed.

The report of the agricultural experiment station of the Duchy of Baden
1909, pp. 157).—This is a report of the station activities for the year
1909. It also contains a history of the station for the last 50 years.

Agricultural-chemical laboratories in Germany, Holland, and Belgium,
I. Lugner (Meddel. K. Landhov. Styr. [Sweden], 1910, No. 5 (152), pp. 29, figs.
3).—A brief description of the above-named laboratories, with notes in regard
to some of the investigations being conducted in them at the present time.

METEOROLOGY—WATER.

1909-10, pp. 18-25).—Observations on pressure, temperature, and rainfall at
the Botanic Gardens, Georgetown, and at various other places in British Guiana
during 1909, and a number of previous years, are recorded and briefly discussed.

Bul., 1910, pp. 66-72, fig. 1).—The sand evaporimeter used consisted essentially
of a metal cylinder 114 mm. in diameter holding about 3 kg. of sand, which
was inclosed in a somewhat larger cylinder containing the water supply and
provided with a graduated gauge for measuring the rate of evaporation.

Observations with this evaporimeter in comparison with a Piche evapor-
imeter during 7 months are recorded. These show a uniformly higher rate of
evaporation from the sand than from a water surface in the Piche evapor-
imeter. The rate of evaporation was reduced by rainfall and increased by east
winds. The evaporation as measured both by the Piche and sand evaporimeters
was decidedly greater than the rainfall during the warmer months of the year.

On the dissolved matter contained in rain water collected at Lincoln, New
Zealand, G. Gray (Separate from Canterbury Agr. Col. Mag., 24 (1910), Nov.,
pp. 12).—This article reports the results of investigations on this subject during
the two years ended June 30, 1909, the investigations being similar to those
made by the author in the years 1884 to 1888.
"The average results obtained during the years 1907–1909 show that the rainfall at Lincoln brings annually to the soil 142.21 lbs. of dissolved matter. Chlorin in the form of common salt is the most abundant constituent, amounting to 34.8 lbs. per acre, equal to a dressing of 57 lbs. of common salt; this amount is sufficient for most ordinary crops. Sulphuric acid, mainly in the form of sodic sulphate, is received to the extent of nearly 19 lbs. per acre. This amount is sufficient for ordinary crops, except perhaps root crops. The nitrogen received as ammonia salts amounts to 0.740 lb. per acre, and that as nitrate to 0.508 lb. per acre. The total nitrogen would be equivalent to a dressing of 9.4 lbs. of nitrate of soda per acre."

Snow limits and climate, V. Paschinger (Mitt. Justus Perthes' Geogr. Austr., 57 (1911), Feb., pp. 57–60, pl. 1).—The variation in depth and distribution of snow in its relation to climate in the northern hemisphere is briefly discussed in this article.

The cycle of water (Rev. Écon. Internat., 7 (1910), II, No. 1, pp. 7–95).—This is a symposium consisting of papers on Filtration Through Sand, by A. Kemna; Sterilization on a Large Scale, by E. Inbeaux; Decantation and Filtration of River Water, by A. C. Houston; and Biological Treatment of Town and Country Sewage, by A. Calmette, which deals quite fully with methods of securing an adequate and safe water supply in town and country and of disposing of sewage. Sewage farming is not considered in itself an adequate means of disposing of large quantities of sewage.

Indispensable conditions for good hygiene of wells, Lomry (Tech. Sanit., 5 (1910), pp. 158–162; abs. in Wasser u. Abwasser, 3 (1911), No. 12, p. 492).—The precautions which must be observed in order to protect wells from contamination with disease germs are briefly set forth.

Mercury vapor lamps and action of ultra-violet rays, F. M. Perrin (Trans. Faraday Soc., 6 (1911), No. 2–3, pp. 199–204, pl. 1, figs. 2).—This article discusses briefly the theoretical principles and practical methods of applying the mercury vapor lamp in the sterilization of water. Its application in the sterilization of other substances, such as milk and butter, is also suggested.

SOILS—FERTILIZERS.

The principles of the circulation of water in cultivated soils and their application, R. d'Andrimont (pp. 117–124).—This is a general discussion of the forms and movements of soil water, especially as related to plant growth.

The movement of nitrates in clay soils, S. Johansson (pp. 149–159).—The author reports and discusses the results of determinations of nitrates, at different dates and depths, in a heavy soil deficient in humus and nitrogen which had received an application of barnyard manure, and also in the drainage water from the soil.

The results bring out clearly the close relation between the amount and movement of the soil water and the distribution of nitrates in the soil. Knowing the water capacity of a soil, it is easy to estimate the depth to which a given rainfall will descend, carrying with it nitrates, and when the evaporation from the surface will cause an upward flow of the water with a consequent rise of the nitrates in the soil.

The types of soils and their importance, S. de Miklaszewski (pp. 276–278).—The author emphasizes the fact that the soil type is determined by the predomi-
nant factor concerned in its formation. Since this varies with each type, it requires that special methods of investigation be used with each soil examined.

The classification of mineral soils according to external characteristics, A. Atterberg (pp. 284-289).—In this paper the author reports results of studies on firmness and plasticity of soils.

To determine firmness the soil was made into 2-cm. cubes, dried at 100° C., and the weight required to split the cubes with a steel spatula noted. On this basis the following classification is proposed: Firmness of 60 to 31 kg., clay; 30 to 16, strong loam; 15 to 8, loose loam; 7 to 6, sand.

As only clay soils are plastic, it is proposed that plasticity be taken as the dividing line between clay and loam soils. Simple methods of determining the degree of plasticity are described, the plasticity being stated in terms of the water content of the soil used in the plasticity test. On the basis of such tests the author divides soils into highly plastic clays, medium plastic clays, and slightly plastic clays.

A tentative division of loam soils into firm and loose loams is given, the firm loams being called clay loams. The sandy soils are divided into coarse sands, fine sands, and silt soils.

The firmness of clay soils is attributed to the extreme fineness of the soil particles. The plasticity, on the other hand, is attributed not only to fineness of particles but to their form as well.

Concerning agrogeological mapping, K. O. Björlykke (pp. 290-296).—This paper discusses the distinctions between geological and agrogeological soil mapping as well as the present status of such work.

The author holds that a soil survey of a region should contain a geographic and orographic exposition; a discussion of climatic relationships and of the agricultural and other industries of the region; geological observations on the soil-forming rocks and the soil surface; a description of the different soil types, their physical and chemical characteristics, and their relation to cultivated plants and to general vegetation; and a discussion of the future agricultural possibilities of the region. The agrogeological maps should be of two kinds, (1) reconnaissance maps and (2) detail maps. The first should include district maps and farm maps.

Red soils (terra rossa), G. Murgoci (pp. 329, 330).—The author here reports limited observations on red soils in Asia Minor. It is believed that these soils are of the same origin as the red soils of southern Europe.

The volumetric constitution of soils (Rev. Sci. [Paris], 49 (1911), I, No. 5, p. 150).—This article calls attention to the volumetric variation of soils containing like proportions of plant nutrients, and emphasizes the importance of some method of expressing the results of chemical analysis on the basis of volume as well as of weight.

Tanks for soil investigations at the Florida Agricultural Experiment Station, A. W. Blair and S. E. Collison (Jour. Indus. and Engin. Chem., 3 (1911), No. 1, pp. 32, 33, figs. 3; abs. in Jour. Soc. Chem. Indus., 39 (1911), No. 3, p. 144, fig. 1).—This article describes a series of soil tanks used to supplement the field work in orange culture, to estimate accurately the loss of soluble fertilizing materials in the drainage waters, and to investigate the effects of long-continued use of commercial fertilizers on the soil and on the orange tree.

Each tank has an inside diameter of 5 ft. 3 in. with a maximum depth of 4½ ft., and a surface area of one-thousandth of an acre. The tanks are constructed of heavy galvanized iron, soldered, riveted, and painted inside and out. The bottom slopes to a point near one side, where a strainer opens into a 2-in. tin-lined drainage pipe a little over 4 ft. long. In each of four corners of a
central collecting pit there is placed a receptacle into which the drainage waters of the tanks are discharged. Connected with these receiving tanks is an overflow tank, to be used in case of emergency, as from long-continued heavy rains. The collecting pit, which is about 8 ft. deep and 6 ft. square, is built of brick with a concrete bottom, and is covered.

The tanks were sunk into the ground to within a few inches of the top and filled with soil to within 3 in. of the edge. The sloping part of the bottom was covered with a layer of smooth quartz pebbles, the coarsest material being placed around the drainage opening. The soil dug from the site which each tank was to occupy was divided into four lots, the top 9 in. forming the first lot, followed by 3 one-foot sections. In filling the tanks the last foot taken from the ground was placed on the gravel in the bottom of the tank, then the next foot was taken, and so on to the top 9 in. The soil was well tamped, each tank containing 8.625 lbs. of dry soil. One orange tree was planted in each tank.

On the influence of shade on the evaporation of water from the soil, C. von Seelhorst (Jour. Landw., 58 (1910), No. 3, pp. 221-228).—Results of observations comparing the evaporation from a loam soil shaded with dry rye plants, and the same type of soil unshaded, show that the shaded soil evaporated 13.9 per cent less of the rainfall than the unshaded soil.

The value of pyritic moor soils as a foundation for drainage structures, G. Fendler and L. Frank (Gsmdhts. Ingen., 33 (1910), No. 49, pp. 877, 878).—In view of the fact that injury to drainage structures at Osambrück had been attributed to the presence of free sulphuric acid in water derived from a moor containing pyrites and the belief that such conditions are more or less general, the author made a series of examinations of samples of water from a moor of this character. He failed to find free sulphuric acid present, the analyses showing the presence of a sufficient amount of carbonates to exclude the possibility of formation of free sulphuric acid.

On the plasticity of clay soils, J. M. Van Bemmelen (Chem. Weekbl., 7 (1910), No. 37, pp. 793–805).—This article summarizes present knowledge regarding the absorption of water by clay, the swelling and shrinking of clay, the formation of colloids in clay by the action of acids and alkalis, the structure of clay, and chemical action in clay soils of varying structure, and discusses various theories of plasticity.

Soil organic matter as material for biochemical investigation, O. Schreiner and E. C. Shorey (Jour. Franklin Inst., 171 (1911), No. 3, pp. 295–300; abs. in Science, n. scr., 33 (1911), No. 844, pp. 339, 340).—This article emphasizes the importance of an exact knowledge of the composition of the organic matter of the soil and describes in outline the methods pursued by the Bureau of Soils of this Department in separating the organic compounds of the soil. See also a previous note (E. S. R., 24, p. 301).

Cholesterol bodies in soils: Phytosterol, O. Schreiner and E. C. Shorey (Jour. Biol. Chem., 9 (1911), No. 1, pp. 9–11, pl. 1).—This work has been previously noted (E. S. R., 24, p. 301), but is here discussed in a more extended manner.

Oxidation in soil, M. X. Sullivan and F. R. Reid (Jour. Indus. and Engin. Chem., 3 (1911), No. 1 pp. 25–30; Chem. News, 163 (1911), Nos. 2673, pp. 73–75; 2674, pp. 88, 89).—The authors describe a method of testing oxidation in soils by means of changes produced in easily oxidizable substances, such as aloin, when brought in contact with the soil, and report investigations on the effects of various factors and treatments on soil oxidation. It is believed that the study of oxidation in soil has considerable value in relation to soil fertility,
since certain factors which favor productiveness favor oxidation. The following conclusions are drawn:

"Soils have the power to oxidize alone. This oxidizing power is increased by adding water to optimum moisture, by the commonly used fertilizers in conjunction with plant growth, by salts and manganese, iron, aluminum, calcium, and magnesium, in the presence of simple organic hydroxyacids.

" Oxidation in soil is comparable to oxidation in plants and animals. The oxidative power of the soil appears to be mainly nonenzymotic, the results of interaction between inorganic constituents and certain types of organic matter. It may be brought about by organic matter in a state of autooxidation and by inorganic oxygen carriers such as manganese and iron.

" Oxidation is greater in the soil than in the subsoil. Oxidation is greater in fertile soils than in infertile soils." (See also E. S. R., 24, p. 223.)

Soils of the eastern United States and their use, I.—The Norfolk fine sandy loam, J. A. Bonsteel (U. S. Dept. Agr., Bul. Soils Circ. 22, pp. 16).—This is the first of a series of circulars, and deals with the geographic distribution, characteristics of soil and subsoil, surface features and drainage, extent of occupation, limitations of uses, tillage requirements, and crop adaptations of the Norfolk fine sandy loam, of which a total area of 4,346,672 acres in 63 different areas in 9 States has been surveyed by the Bureau of Soils.

Soils of the eastern United States and their use, II.—The Norfolk fine sand, J. A. Bonsteel (U. S. Dept. Agr., Bul. Soils Circ. 23, pp. 16).—This is the second of a series of circulars noted above, and deals with the Norfolk fine sand, of which a total area of 1,595,672 acres in 46 different areas in 11 States has been surveyed by the Bureau of Soils.

[County geological surveys in Iowa], M. F. Arex, T. H. MacRide, S. W. Stookey, and B. Shimek (Iowa Geol. Survey Ann. Rpt., 20 (1909), pp. 1-542, pls. 42, figs. 42, maps 10).—Geological surveys of Butler, Grundy, Hamilton, Wright, Iowa, Wayne, Poweshiek, Harrison, Monona, and Davis counties are reported. These reports deal not only with the physiography, stratigraphy, and economic products, but also contain important sections relating to soils.

Soil observations in Istria: Red soils (terra rossa), Wilhelm Graf zu Leiningen (Naturw. Ztschr. Forst u. Landw., 9 (1911), No. 2, pp. 65-89, figs. 2).—This article reports observations on the influence of weathering and soil formation on vegetation in Istria, and on the extent, formation, and origin, and the physical and chemical properties, of the red soils (terra rossa) of that region. It is stated that these soils are derived principally from the residue of limestone rocks, and to a less extent of flysch (sandstone). In the process of formation the calcium and magnesium are washed away, leaving the aluminum and iron compounds to form the red soil.

Typical red soils are fine-grained, impervious, and retentive of moisture. Mechanical analyses are reported which showed from 66 to 81.4 per cent of clay. Chemical analysis of a typical sample showed water and organic matter 11.77, silica 47.79, ferric oxide 32.24, alumina 3.15, manganic oxide 1.35, lime 0.68, magnesia 1.37, potash 1.15, soda 1.56, and phosphoric acid 0.24 per cent. As the analysis shows, these soils are deficient in lime. They are therefore benefited both chemically and physically by liming.

Some results of a flying soil survey, B. C. Arson (Jour. New Zeal. Dept. Agr., 2 (1911), No. 1, pp. 10-17, figs. 6).—This article summarizes the more important results presented in a former report on the soils of the subantarctic islands of New Zealand (E. S. R., 24, p. 19), calling attention to the unusually high nitrogen content of the soils and to the fact that the quality of the soils is closely correlated with the character of the vegetation, each soil type corresponding to a characteristic flora.
Influence of the soil on the composition of some plants, J. M. M. Dormaar, (Meded. Procifstd. Java-Sukerindus., 1909, No. 23, pp. 535–539; abs. in Chem. Zentbl., 1909, II, No. 3, p. 639; Chem. Abs., 5 (1911), No. 6, pp. 1147).—Various plants were grown on volcanic ash and clay soil, and the total nitrogen, albuminoid nitrogen, moisture, crude fiber, ash, and ash constituents were determined in the mature plants. The plants made better growth on clay than on the volcanic ash, and contained more phosphates, sulphates, chlorids, and potash, but less lime.

Investigations on the value of root residues of various plants as nitrogen collectors and green manure, E. Hotter, E. Herrmann, and J. Stumpf (Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 2, pp. 152–171).—Investigations similar to those of Werner and Weiske to determine the fertilizing effect of the roots of alfalfa, red clover, vetch and oats, grasses, corn, winter wheat, and oats, as compared with fertilizers containing nitrate of soda, are reported. The weights and composition with reference to fertilizer constituents of the above-ground and underground portions of various crops of these plants are given, as well as the yields of winter wheat and oats following the turning under of the roots of the leguminous plants or applications of fertilizers containing nitrate of soda.

The results show in general that the turning under of the roots of the leguminous plants produced as large an increase in yield the first year as the application of normal amounts of nitrate of soda, and that the beneficial effect was appreciable during two succeeding years, whereas there was no effect of the nitrate of soda after the first year.

The analyses showed that the root residues of the alfalfa supplied about 267.76 lbs. of nitrogen per acre during four years, of the red clover 151.73 lbs. per acre during 2 years, and of the vetch and oats 89.25 lbs. during 1 year, more than enough to supply the needs of maximum crops of cereals.

The authors conclude that by following a rotation in which from one-fifth to one-sixth of the total area is kept in leguminous plants, the stubble of which is turned under, the total amount of nitrogen required in grain farming can be supplied, without resort to the use of nitrate of soda. At the same time the above-ground portion of the leguminous crops can be fed to stock, the manure from which will furnish an additional supply of nitrogen.

On the penetration of fertilizers into the soil, A. Demolon and G. Broquet (Stu. Agron. Alins Bul., 1919, pp. 73–37, figs. 2).—Observations on the rate of diffusion and depth of penetration of sodium chlorid in sand and clay, and of sodium nitrate in garden soil, showed that even in sand the rate of diffusion of sodium chlorid is very low, while the clay showed very strong absorbent power for the chlorid. The rate of diffusion of nitrate of soda in loam soils was much less than is generally assumed. There is apparently little danger of loss of nitrates in strong soils during the period of plant growth. In view of the slow rate of diffusion shown by these investigations the author strongly urges the necessity of thoroughly mixing even the more soluble fertilizers with the soil to a considerable depth.

The use of nitrate of soda in commercial fertilizers, C. S. Cathcart (Jour. Indus. and Engr. Chem., 3 (1911), No. 1, pp. 30–32).—In view of the fact that fertilizer manufacturers give as the principal reasons for the comparatively limited use of nitrate of soda in mixed fertilizers (1) the loss of nitrogen in mixtures containing the nitrate, and (2) the unfavorable mechanical condition of such mixtures, the author made a series of experiments which showed that the loss of nitrogen from mixtures containing nitrate is not of great importance if the materials are kept dry, but that there is an appreciable loss when the mixtures absorb moisture. The experiments also showed that fertilizer mix-
tures containing as much as 2.5 per cent of nitrogen and 10 per cent of potash may be stored under severe weather conditions without serious deterioration in mechanical condition provided sulphate of potash is used. Mixtures containing muriate of potash deteriorate in mechanical condition after having been stored for a short time.

A study of the composition, toxicity, and chemical and biological evolution of crude ammonia, A. Demolon and G. Broquet (Sta. Agron, Aisne Ball., 1910, pp. 92-118).—Crude ammonia, a by-product of gas manufacture, is stated to be a complex mixture of various forms of nitrogen, the most important being ferrocyanids. Sulphocyanids are sometimes present in small amounts. Sulphur, much of it in free state, is always an important constituent of the material.

The crude ammonia is practically unaffected by such natural physical agencies as moisture, oxygen of the air, etc. It varies in toxic properties largely in proportion to the amount of sulphocyanids present. The toxicity disappears slowly in moist air, but more rapidly in contact with the soil. The ammoniacal nitrogen in the crude ammonia is readily assimilated by micro-organisms. The sulphocyanids are more slowly disposed of in this way, while the ferrocyanids are still more resistant.

Preliminary report on the peat deposits of Florida, R. M. Harper (Fla. Geol. Survey Ann. Rpt., 3 (1910), pp. 197-366, pls. 13, figs. 1).—This report deals with the conditions of formation, distribution, classification, composition, and utilization of the peat deposits of Florida. The use of these peat deposits for fertilizer and fertilizer filler and as agricultural soils is referred to. A bibliography of the subject is given.

Potash salts of Galicia, F. J. Machalske (Amer. Fert., 34 (1911), No. 6, pp. 17-23).—The potash deposits of Galicia are described and compared with those of Germany. It is shown that large and rich deposits of potash salts occur in the eastern part of Galicia, especially in the vicinity of Kalusz, and that conditions are now favorable for their exploitation.

Phosphate deposits of Egypt (Ibid. Trade Jour. [London], 72 (1911), No. 746, pp. 573, 574).—Brief accounts are given of deposits in the Nile Valley, the Red Sea hills, and the Dakhlia Oasis. These phosphates are as a rule of low grade but may become commercially important.

Constitution of Thomas slag, H. Blomé (Metallurgie, 7 (1910), pp. 659-667, 698-705; Stahl u. Eisen, 30 (1910), p. 2161; abs. in Jour. Soc. Chem. Indus., 29 (1910), No. 24, p. 1167; Chem. Ztg., 35 (1911), No. 21, Report., p. 78).—The author investigated the cause of the increase in citrate solubility resulting from the fusion of Thomas slag with sand. He succeeded in producing a fusion of tetracalcium phosphate and calcium orthosilicate which was practically completely soluble in 2 per cent citric acid. His investigations indicate that this increase in solubility is due to the formation of the double compound shown by Stead and Ridsdale to have the composition of 4CaO, P2O5+SiO2 with a melting point of 1,700° C.

On the action of an addition of alumina and silicic-acid gels to the soil on the assimilation of phosphoric acid by plants, T. Preiffer and E. Blanck (Mitt. Landw. Inst. Breslau, 6 (1911), No. 2, pp. 315-324).—Experiments are here reported in which pots containing 17 kg. of pure sand received a basic fertilizer of 3 gm. of potassium phosphate and 50 cc. of water extract from a
sandy lupine soil, alumina and silica being added at rates of 385 and 234 gm., respectively. Yellow lupines were grown in the pots.

The results show that the alumina and silicic acid gels reduced the yield of dry matter and the phosphoric acid content of the plant. Freezing and the addition of calcium chloride had no effect. Heating reduced the yield of dry matter and probably the phosphoric acid assimilation. The results indicated that phosphoric acid did not enter into adsorptive but into chemical combination.

Manganese causing bare patches in soil (Agr. Gaz. N. S. Wales, 22 (1911), No. 1, p. 70).—It is stated that superphosphate almost fully corrected the toxic condition of soils in which an excess of manganese (0.24 per cent of MnO₂) had completely killed the grass.

Manganese in field experiments, H. Bartmann (Jour. Agr. Prat., u. scr., 20 (1910), No. 47, pp. 666, 667).—The results are given of tests with manganese salts on the yields of turnips, beans, peas, Irish potatoes, corn, and sugar beets. The yields of potatoes and sugar beets were found to be increased by the use of the manganese salts, reaching the optimum when from 176 to 352 pounds per acre was used.

Columbus municipal garbage reduction plant. I. S. Osborn (Amer. Fert., 34 (1911), No. 6, pp. 44-48, figs. 9).—The construction and operation of this plant, which can dispose of 160 tons of garbage per day and produces as a final product garbage tankage fertilizer valued at about $10 per ton, are described. The sale of this fertilizer and of the garbage grease obtained more than pays the cost of operation of the plant.

Fertilizer trade, R. F. Chase, F. I. Bright, and J. White (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 67, pp. 1094, 1095).—Statistics are given of the fertilizer trade in the United Kingdom, Brazil, and the United States.

It is stated that the value of the fertilizer imports into the United States during the year ended June 30, 1910, was $8,371,883, of the exports $8,700,610. These figures do not include imports (1) of nitrate of soda from Chile, which amounted to $16,601,328 in the calendar year 1910, about one-third of which was used for fertilizer, (2) of sulphate of ammonia, which amounted to $4,668,820, chiefly from England, nor (3) potash, which amounted to $8,363,623, mainly from Germany, and a very large portion of which was used as fertilizer.

Commercial fertilizers in the South (Amer. Fert., 34 (1911), No. 6, pp. 26, 27; Manufrs. Rec., 59 (1911), No. 11, p. 47).—The rapid increase in consumption of fertilizers in the South is noted, and it is stated that 3,607,817 tons were consumed in 12 southern States during 1910.

Licensed commercial fertilizers, 1911. F. W. Woll (Wisconsin Sta. Circ. Inform, 24, pp. 11, 12).—A list of manufacturers and brands licensed for the year 1911.

AGRICULTURAL BOTANY.

Action of nitrogen-fixing bacteria in the earth, A. V. Krainski (Dnevn. XII. St’’@za Russ. Est.-Isp. i Vrach. [Moscow], 1910, No. 10, p. 652; abs. in Zentral. Biochem. u. Biophys., 10 (1910), No. 17-18, pp. 817, 818; Chem. Abs., 5 (1911), No. 3, p. 556).—In experiments with different soils the author found that the fixation of free nitrogen occurs in the soil by means of micro-organisms. The greatest amount of fixation occurred in damp, but not wet, well aerated, sandy soils where for one part of nitrogen assimilated, 90 parts of carbon were used by the bacteria. In sand cultures with Azotobacter chroococcum, it was found that 10 mg. of nitrogen were fixed per gram of mannite consumed.
Inoculation experiments on different legumes with Azotogen, nitragin, and infected soil, H. von Feilitzen (Centbl. Bakt. [etc.], 2. Abt., 29 (1911), No. 6–8, pp. 198–205, pls. 7, figs. 2).—The results are given of experiments with soy beans, yellow and blue lupines, sarradella, and hybrid clover grown in new moor soils, in which Azotogen (a new trade preparation of legume tubercle bacteria), nitragin, and soil previously grown to the same legume (soy bean excepted), were used as inoculating materials.

The soil infections showed the usual beneficial results, except in the case of the soy bean plant, where no tubercles were formed, as the inoculating soil was from garden beans (Phaseolus vulgaris). The Azotogen cultures gave very favorable results on all the legumes, while the nitragin gave poorer and less certain results than either of the others.

In the presence of disodium phosphate the amount of catalase increases. Monopotassium phosphate decreases the amount of catalase while dipotassium phosphate destroys it. The different phosphates act similarly on reductase. Since the different phosphates act in a similar way on the alcoholic ferment, catalase and reductase may be considered as anaerobic ferment, but the fermentative nature of both are to be given further study.

Observations on the growth and energy of germination of cereals, V. Viner (Otech. Shatatol. Sel'sk. Khov. Opityu. Shtatstii, 3 (1909), pl. 2, pp. 90–109; abs. in Zhur. Opityu. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 2, pp. 263, 264).—Studies were made on the vitality and viability of seeds, principally of oats, from which it was found that the growth was intimately related to the size and absolute weight of the seeds, while the rapidity of germination was determined by the degree of ripeness and plumpness of the grain.

Concerning the selective permeable membrane of wheat grains, H. Schroeder (Flora, 102 (1911), No. 2, pp. 186–208, figs. 4, dyn. 1).—The author reports studies made on the permeability of the seed coats of wheat with a number of different solutions, the results confirming in the main those of Brown as to the existence of a selective permeable membrane (E. S. R., 18, p. 727; 21, p. 126).

The rôle of living cells in the ascent of water in plants, P. A. Rosshart (Bot. Centbl., Reihe. 25 (1910), 1. Abt., No. 3, pp. 243–375, figs. 2; abs. in Jour. Roy. Hort. Sc. [London], 36 (1910), No. 2, pp. 474, 475).—The author carried on experiments with about 800 plants, representing 131 different species, in which he studied the assistance given by the living cells of the stem and petiole in the ascent of sap.

Portions of stems and petioles were killed by means of steam, ether, or xylol. When this was done the distal portions withered after a greater or less interval. The water was found to pass through the dead portion, although in greatly reduced quantity. The withering of the leaves is held to show that some of the living cells were killed. The longer the portion of stem or petiole killed the sooner the withering took place. Plants of the same species, and in the same stage of growth, withered in the same time if the part of the stem or petiole killed was of the same length. Younger portions were found to perish sooner than older ones. In none of the plants was there any trace of injury either to the stem or leaves below the portion killed by steam, ether, or xylol.

98334°—No. 2—11——3
The author claims that the living cells of the stem and petiole must give some active help in the ascent of water, but that the amount of help so given varies in different plants.

The relation of transpiration to the water content of leaves in the ocotillo, F. E. Lloyd (Science, n. ser., 33 (1911), No. 830, p. 191).—During the summer of 1910 the author made a study of transpiration in the ocotillo (Foquiera splendens).

It was found that the ratio between the intake and outgo of water was not constant, but that during the day the outgo was greater than the intake. The reversed relation obtained during the night. The amount of water relative to the dry weight of the leaves decreased until some time in the early part of the afternoon, after which it was found to increase until about 4 a. m. The decrease of water in the leaf occurred during the period of the opening of the stomata, and these organs were therefore not found closely regulatory of the rate of transpiration.

Light as a formative factor in the habit of growth of Asparagus plumosus, F. C. Newcombe (Science, n. ser., 33 (1911), No. 840, pp. 196, 197).—The shoots of this plant are said to grow erect for a time, and then turn their tips to the horizontal position. This bending is geotropic, but it is greatly influenced by the presence of light. Where shoots were so covered as to exclude the light the bending was delayed, and where subterranean buds were covered and caused to grow without ever being in the light the horizontal bend was never complete, but there were mutations through an arc of 20 to 50°.

This behavior is attributed to one of two hypotheses. Either the etiolation disarranges the normal processes, or there is a weak inheritance of diageotropicism which needs the supporting influence of light to give the usual form to the plant.

Respiration in air, in nitrogen, and in hydrogen, B. M. Duggar and G. R. Hill, Jr. (Science, n. ser., 33 (1911), No. 842, p. 261).—A brief account is given of experiments relating to the rate, continuance, and decline of anaerobic respiration or carbon dioxide production in nitrogen and hydrogen as compared with aerobic respiration under otherwise similar conditions. The plant materials used were slices of sugar beet and germinating seed.

Respiration and fermentation, V. I. Palladin (Dnev. XII. Sta. Vrach [Moscow], 1910, No. 3, p. 14; abs. in Zhur. Op'ytn. Agron. (Russ. Jour. Expt. Landw.). 11 (1910), No. 1, pp. 126, 127).—The experiments of Stanevich are said to have shown that the treatment of wheat seedlings with different solvents, such as acetone, chloroform, alcohol, etc., affects the process of their setting free carbon dioxide and exerts an influence on the extraction of lipoids. From this the author concludes that one of the stages of alcoholic fermentation consists in the combination of glucose with phosphoric acid, and that lipoids act as conservators of the phosphoric acid required for that process. Lipoids are considered necessary for the anaerobic stage of respiration as well as for alcoholic fermentation.

On the basis of his experiments the author assumes that the chromogen in the etiolated leaves of the bean is present in a combined state, as can be determined by pouring over wheat seedlings extracts of the etiolated leaves em-
ployed in the experiments mentioned above. After 24 hours the wheat seedlings blacken, owing to the fact that they decompose the substances which bind the chromogen in combination and afterwards oxidize it. The action is held to be due to the presence of ferments in the seedlings.

When etiolated leaves of the beans were subjected to autolysis in water the formation of chromogen was noted, this also indicating that it exists in a combined state. It is thought that probably the chromogens appear in combination with the glucosids. This is submitted as a hypothesis, and the author proposes calling the compound "prochromogen."

The photochemical synthesis of carbohydrates in the absence of chlorophyll, J. Stoklasa and W. Zdobnicky (Biochem. Ztschr., 30 (1911), No. 6, pp. 433-456, pl. l, fig. 1).—In a previous paper (E. S. R., 24, p. 431) the authors announced the synthetic formation of carbohydrates under the influence of ultraviolet rays and in the absence of chlorophyll. In the present publication a detailed account of their investigations is given.

The authors found in experiments with ultraviolet rays that there was no formaldehyde nor carbohydrates formed from carbon dioxide and water in the absence of potassium hydroxid. From water vapor and carbon dioxide in the presence of potassium hydroxid, formaldehyde was formed but no carbohydrates. Neither formaldehyde nor carbohydrates were produced from carbon dioxide and non-nascent hydrogen in the presence of potassium hydroxid, and in the absence of the ultraviolet rays formic acid was formed from carbon dioxide and nascent hydrogen in the presence of potassium hydroxid. From carbon dioxide and nascent hydrogen in the presence of potassium hydroxid sugar was formed under the influence of the ultraviolet rays.

The authors have shown the synthesis of sugars from potassium bicarbonate and nascent hydrogen, and from their investigations they conclude that pure carbonic acid is not reduced in the presence of nascent hydrogen in the chlorophyll-bearing cell, but that the reduction takes place through the production of potassium bicarbonate formed within the cell. In the presence of this potassium the formaldehyde is condensed into carbohydrates.

Chlorophyll in living chloroplasts, D. I. Ivanovski (Dnevn. XII. 8"zda Russ. Est.-Isp. i Vrach [Moscow], 1910, No. 7, p. 269; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 1, p. 126).—The author notes that the chlorophyll of the living leaf differs from that of an alcoholic or other extract in the position of the absorption bands, in the degree of stability in light and air, and in the dissimilar behavior toward solvents. An investigation is reported on the unequal behavior of the chlorophylls to light and to solvents.

The experiments led to the conclusion that the hypothesis that chlorophyll in living leaves is constantly destroyed and reformed must be modified, as there appears to be no regeneration of chlorophyll in mature leaves. The stability of the chlorophyll of the living leaf in light and air may be accounted for by assuming that in living chloroplasts the chlorophyll is present in the colloidal state. Experiments have shown that chlorophyll in colloidal solution possesses considerable stability in light and air. This assumption will account for the peculiar behavior of chlorophyll of living leaves to solvents.

The author believes that possibly it is in the colloidal chlorophyll that the process of decomposition of carbon dioxide takes place.

The correlation between the osmotic pressure of nutrient solutions and the development and chemical composition of plants, N. K. Maliushchitski (Dnevn. XII. 8"zda Russ. Est.-Isp. i Vrach [Moscow], 1910, No. 9, p. 414; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 1, pp. 122-124).—During the years 1903 to 1907 cereals were grown in sand cultures
with a normal nutrient solution to which were added various compounds of calcium, potassium, sodium, and magnesium, comparisons being made between each individual salt. The solutions were made isotonic, while in another series the strength of the solutions was raised to the same degree of isoconcentration.

The author found that when isotonic solutions were used the plants resembled one another in external appearance, in the amount of dry matter, and in anatomical characters, as well as in the percentage of nitrogen they contained. When, on the other hand, the plants were grown in isoconcentrated solutions, especially in the case of such salts as magnesium sulphate and sodium chloride, the plants differed not only in their nitrogen content but in other respects.

In 1905 sugar beets were grown in soil cultures in which the osmotic pressure of the soil solutions was raised either by lowering the amount of water in the vessels or by introducing corresponding amounts of sodium chloride. In both cases the beets had the same sugar content, from which the conclusion is drawn that by making use of the osmotic pressure of the nutrient solutions, other conditions being equal, it is possible to regulate not only the total yield of dry matter, but, within certain degrees, its chemical composition.

In 1907 experiments were made with oats and millet, from which it is concluded that (1) when the amounts of water are equal and the concentrations and the amounts of nutrient substances differ the assimilative activity of the leaves increases with the increase of concentration, (2) when the concentrations are equal the assimilative activity of the leaf increases with the amount of water and the nutrient substances, and (3) when the amount of nutrient salts is equal and the water and concentrations differ the assimilative activity of the leaf diminishes.

The influence of sugar solutions of different degrees of concentration on the respiration, turgescence, and growth of cells, A. Maige and G. Nicolas (Ann. Sci. Nat. Bot., 9. ser., 12 (1910). No. 2–6. pp. 315–363).—A study is reported on the effect of different dilutions of saccharose, maltose, lactose, glucose, and levulose on the respiration, turgescence, and growth of bean seedlings. The beans were sprouted and in an etiolated condition were transferred to solutions of the different sugars and the carbon dioxide, oxygen, and respiratory coefficients determined.

The sugar solutions were found to have an osmotic and plasmolytic effect, retarding growth, or to penetrate and diffuse in the cell. The penetrating power was found to vary with the different sugars, and the osmotic action of solutions of equal concentration varied with their penetrating power. All sugar solutions were found to modify respiration after penetrating the cells. The influence of a given sugar on a plant will depend on its penetrating power, its osmotic activity, and its specific action on the chemism of respiration. Sugars of the same group differ little in their specific action, and for equal concentrations their activity is in direct relation to their penetration, saccharose being more active than maltose, and maltose more so than lactose, glucose, and levulose.

The absorption of nutritive substances from the soil by the sunflower in connection with the formation of organic matter, I. Konovalov (Separate from Izv. Klev. Politekh. Inst., 1908, pp. 143; abs. in Zhor. Opytn. Agron. (Russ. Jour. Expt. Landw.), 11 (1910), No. 2, pp. 266–268).—After a review of the literature relating to the absorption of mineral salts and the increase in organic matter in various plants under cultivation, a description is given of experiments with several varieties of sunflowers, in which the dry matter was determined at intervals of from 5 to 8 days from the time of the sprouting of the seed to the ripening of the plant.

In all the varieties the process of increase of organic matter proceeded approximately in like manner. When the flowering heads were being formed,
from one-third to one-half of the total organic matter of the plants had been accumulated. With the development of the heads there was a translocation of the plastic material, first from the leaves and then from the stems to the heads. The growth of the vegetative organs was completed before the formation of the flower heads. In the ripe heads the seeds constituted one-half of the dry weight of the head.

It was found that the total nitrogen, the albuminoid nitrogen, and the nitrogen occurring in asparagin and organic bases varied during the different stages of growth, the nitrogen being mostly in the leaves during the first half of the growing period, while in the second half it was found in the flower head. The formation of asparagin took place to a greater extent during the first stages of the formation of the head, when the decomposition of the albuminoid nitrogen was rapidly taking place.

The mineral matter was found most abundant in the leaves, and it was present in greatest quantity during the period of formation and flowering of the heads. In the stems the ash content was the highest during the first half of development, while in the heads it was greatest during flowering.

In comparing the sunflower with other plants it was found that the sunflower needs more nutritive material than cereals or clover, but less organic matter than either.

In regard to the water requirements of the sunflower, these were found to be the greatest from the time of sprouting to the development of the sixth or eighth leaf, after which, by the deep penetration of the root system, the plant can thrive in relatively dry soils.

The assimilation of phosphoric acid by plants, I. Pouget and D. Shushilak (Zhur. Opym. Agron. (Russ. Journ. Expt. Landw.), 11 (1910), No. 6, pp. 825-831).—Experiments are reported on the assimilation of phosphoric acid by wheat seedlings grown in water cultures to which different amounts of potassium phosphate were so added as to make the quantity of phosphoric acid vary from 0.05 to 4 mg. per liter of solution.

For the concentrations varying from 1.1 to 4 mg. the assimilation of phosphoric acid was in direct proportion to the strength of the solution. In concentrations of 1 to 0.137 mg. no direct relation was observed to exist between the taking up of the phosphoric acid and the strength of the solution.

No relation was found to exist between the amount of water evaporated by the plant and the amount of phosphoric acid taken up by it, and under the conditions of the experiment phosphoric acid was taken from the solution more rapidly than the water, the concentration being proportionately reduced, except that where the weaker solutions were employed, as from 0.1 to 0.05 mg., there appeared to be an increase in the amount of phosphoric acid in the solution. This was believed to be due to an exudation from the roots, the phosphoric acid probably existing in the plant in the form of a complex organic compound.

The lime requirements of plants, N. I. Konovalov (Ducen, XII, 8'"Gzda Russ. Est.-Isp. i Vrach [Moscow], 1910, No. 9, p. 391; abs. in Zhur. Opym. Agron. (Russ. Journ. Expt. Landw.), 11 (1910), No. 1, pp. 107, 108).—The results of the author's investigations indicate that the development of millet, oats, wheat, lupines, etc., is dependent on the amount of calcium present in the nutrient solution. He states that the theory of Loew, while ascribing essential importance to the ratios of calcium to magnesium, does not give sufficient attention to the amounts of these substances required by plants.

The influence of manganese on the development of Aspergillus niger, G. Bertrand and M. Javiller (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 4, pp. 225-228).—A preliminary report is given of investigations with
A. niger to determine the effect of increased quantities of manganese on its development.

In the experiments different quantities of manganese sulphate were added to the medium in which the fungus was grown, and the dry weight of the fungus as well as its ash content increased with the increased concentration of manganese up to the pots receiving 1,000 mg. per liter. When the amount exceeded this proportion there was a rapid falling off in the growth of the plant. The amount of manganese fixed, unlike that of some other substances, was not in direct proportion to the quantity contained in the nutrient solution.

The effect on plants of certain substances extracted from coal tar, M. M. Mirande (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 4, pp. 204-205).—In a previous note (F. S. R., 24, p. 631) the author called attention to the physiological action of vapors arising from tar used on roads as affecting plants.

In the present paper he gives the results of an investigation of the effect on plants of a number of commercial products, such as carbonyle, carbolineum, carbonéine, etc., which are derived by distillation from coal tar. All of these contain creosote in some form, and a number are used as insecticides and for other purposes. The author finds that they are more or less injurious, causing the destruction of the green cells with which they come in contact. On account of their injurious properties he urges great care in their use when applied to living plants.

Intumescences on foliage leaves produced by poisons, Lilly M. Marx (Österr. Bot. Ztschr., 61 (1911), No. 2-3, pp. 49-59, pl. 1, fig. 1).—The author claims as a result of her investigations that the leaves of Goldfussia anisophylla, which had been sprayed with ammonium copper carbonate or a 0.1 per cent alcoholic solution of corrosive sublimate, developed under sufficient warmth and moisture conditions leaf intumescences. If any of these factors (poison, warmth, and moisture) were wanting, no intumescences resulted. The formation of these outgrowths is entirely independent of light or darkness, but the age of the leaf plays a very important rôle, as very young leaves and leaves fully matured did not react to the poisons. Similar results were also obtained with cauliflower and Conocephalus avicus.

Some effects of severe freezing upon vegetation in a condition of active growth, F. K. Butter and C. O. Rosendahl (Science, v. ser., 33 (1911). No. 826, p. 261).—The authors state that on the night of April 15, 1910, the temperature at Minneapolis fell to 27° F. and a week later to 19° with a high wind. At the time of these frosts vegetation was in an advanced state, and many trees were in full leaf while nearly all others were in active growth.

Observations were made upon about 70 species of woody and herbaceous plants, and it was found that besides the injury due to cold, much mechanical injury resulted from loss of turgidity in succulent young shoots during the early stages of freezing, and from the extreme brittleness of hard frozen leaves and twigs which the wind snapped off in great numbers. The second freeze injured many plants which were not hurt by the first one. About 42 per cent of the woody species lost practically all their foliage, only about 10 per cent being relatively uninjured. Mature leaves and those just unfolding from the bud were less injured than half-grown leaves of the same plant. In about 60 per cent of the species examined the twigs of the new growth were killed or severely injured, and in about 15 per cent the twigs of the previous season's growth, and in a few instances older twigs, were destroyed. Flower buds were somewhat more tender, and open flowers and fruits much more tender, than vegetative parts. The damage to native herbaceous plants was mainly mechanical and relatively slight except in the case of open flowers and developing
fruits. A few weeks after the freezes the herbaceous vegetation appeared normal, while the woody plants had just begun to recuperate.

The usual types of recuperation in trees and shrubs were a new crop of leaves when the twigs were uninjured and the terminal bud intact, the appearance of lateral shoots from the leaf axils of uninjured portions when the distal portions of the twigs were destroyed, and by the starting of growth from latent buds upon woody twigs, some of which were several years old. In some cases all these methods of regeneration appeared on the same plant.

**Evaporation in its relation to the prairie problem**, B. Shimek (Science, n. ser., 33 (1911), No. 840, p. 192).—Attention is called to the fact that surfaces exposed to the south and southwest in the Mississippi Valley are usually treeless and that where changes in topography are abrupt the transition from forest to prairie is likewise abrupt. Field operations on the rate of evaporation on treeless and forested areas have been made, and the results of these observations show that evaporation increases with the temperature and the velocity of the wind and that when the temperature is high the fluctuations in evaporation are caused by changes in wind velocity.

The bearing of these results upon prairie formation is discussed.

**An isolated prairie grove and its ecological significance**, H. A. Gleason (Science, n. ser., 33 (1911), No. 840, p. 192).—A description is given of a prairie grove in Champaign County, Ill., about 1 by 3 miles in size, which is located at some distance from a stream. The prevailing trees in the grove are oaks, hickories, and black walnuts, with scattered individuals of other species. The variation in the composition of the forest indicates that it migrated into this region from the northeast. The grove is not continuous, but is broken by areas of low ground which contain permanent standing water.

It is concluded that formerly the whole moraine was covered with forest, but that since the introduction of prairie fires all has been destroyed but this grove, which is protected by standing water. The general conclusion is drawn that forests were formerly of much wider extent in Illinois than at present, but that the prairies do not owe their origin to prairie fires.

**Twin hybrids in Enotera**, with a suggestion concerning their explanation, R. R. Gates (Science, n. ser., 33 (1911), No. 842, p. 262).—By means of a large number of crosses the type of behavior in Enotera called by de Vries twin hybrids has been confirmed, and many new crosses which had not previously been reported have been made. The author describes the results of a number of cross pollinations and the forms produced, and gives an account of cultures from wild seeds, which indicate that there is a marked dimorphism of some of the forms in the wild condition. This may account for the occurrence of similar twin types in crosses in which E. bicinis is the female parent, the condition being transmitted in the eggs, but not usually through the pollen.

**Cryptomeric inheritance of Onagra**, C. S. Gager (Science, n. ser., 33 (1911), No. 840, p. 191).—Attention is called to an abnormal plant of O. bicinis that appeared in a pedigreed culture following exposure to radium rays of the ovule employed in producing the plant.

The plant possessed two primary shoot systems of equivalent value but entirely unlike in morphological characters. The effect was believed to be due to the exposure to the radium rays, although this was not conclusively shown. Hybrids produced between the two unlike halves manifested in the F₁ and F₂ generations the characters of only one of the parent shoots, and this is held to indicate that the inheritance of a character and its expression are quite different phenomena.

**Reversible sex mutants in Lychnis dioica**, G. H. Shull (Science, n. ser., 33 (1911), No. 840, p. 192).—The author describes the discovery in 1908 of hermaph-
rodite mutants of L. dioica, and the obtaining the following year the first generation cross of these with females and normal males. In the present paper data are presented of more than 100 families in which these hermaphrodites were used, most of the families representing the second generation from the originals.

It is shown that the hermaphrodite character is a modified male condition, not due to the presence of an independent modifying character, but obviously to a modified condition of the male-producing gene. This character is not transmitted by the egg, but only by the sperm. Among the offspring of these hermaphrodites there have appeared a few normal males in such proportions that they can only be considered as male mutants, since they also breed true to their male character. The appearance of hermaphrodite mutants in families produced from normal males and the appearance in turn of male mutants in families produced by hermaphrodites suggest reversible modifications of a single gene rather than the addition of one to those previously present, and a subtraction of a gene from them. These results are held to have an important bearing upon the “presence and absence” hypothesis.

FIELD CROPS.

The history of cultivated plants, L. Reinhardt (Kulturgeschichte der Nutz-pflanzen. Munich, 1911, vol. 4, 1, half, pp. 738, pls. 90, figs. 57; 2, half, pp. 756, pls. 76, figs. 35).—This volume forms part of a work published under the title of Die Erde und die Kultur.

The first part of the volume treats of the cereal grains, fruits, vegetables, oil plants, sugar-producing crops, plants from which condiments are derived, plants furnishing narcotic principles, and the organisms producing fermentation. The second part is devoted to forage, fiber, dye, tannin, rubber, resin, perfume, drug, and ornamental plants, and also treats of the species of trees serving as sources of wood and lumber, the valuable desert plants, and the more important diseases and insect enemies of cultivated crops.

Theory and practice of plant breeding, II. Lang (Theorie und Praxis der Pflanzenzüchtung. Stuttgart, 1910, pp. VIII+169, figs. 47).—This book, intended for practical farmers and students, discusses the following topics: The technical equipment of plant breeders, propagation, variability, and inheritance, selection, the breeding of special crops, including wheat, rye, barley, oats, fodder beets, potatoes, maize, red clover, and tobacco, and the protection of the plant breeder against illegitimate competition.

Contribution to the history of wheat, the sugar beet, Jerusalem artichoke, and potato, P. de Vilmorin (Rev. Gén. Agron., n. ser., 5 (1910), No. 8, pp. 289-305).—This address contains historical data on certain crops and citations of French writings on the subject.

Wyoming forage plants and their chemical composition, H. G. Knight, F. E. Hepner, and A. Nelson (Wyoming Sta. Bul. 87, pp. 3-152, figs. 44).—In continuation of work previously noted (E. S. R., 20, p. 135), tables are given stating the analyses of various grasses, sedges, rushes, and other plants collected at different altitudes (4,100 to 11,000 ft.) in recent years, and miscellaneous analyses of barley, corn, emmer, and native hay.

Analyses are reported for the following plants and descriptions given of many of them: Bearded wheat grass (Agropyron caudatum), western wheat grass (A. occidentale), western couch grass (A. pseudocespitum). Scribner wheat grass (A. scribneri), slender wheat grass (A. tenuifolium), red top (Agrostis rubra), rough hair grass (A. hyemalis), tufted bent grass (A. humilis), Colorado sand grass (Andropogon hallii), little blue joint (A. scoparius), long awned aristida
(Aristida longiseta), tall grama grass (Atheropogon euritipendula), grama grass (Bouteloua oligostachya), slough grass (Beckmannia eucraeformis), Porter brome grass (Bromus porteri), Richardson brome grass (B. richardsonii), barren brome grass (B. stenillos), buffalo grass (Buchloe dactyloides), Canada bent grass (Calamagrostis canadensis), purple reed bent (C. purpurascens), long leaved reed grass (Calamovilfa longifolia), water whorl grass (Catabrosa aquatica), green foxtail (Chasbioidea viridis), tufted hair grass (Deschampsia cespitosa), alkali grass (Distichlis spicata), early bunch grass (Eutopia obtusata), Canadian wild rye (Elymus canadensis), giant rye grass (E. condensatus), Indian millet (Eriocoma cspadita), King fescue (Festuca con- finis), sheep fescue (F. ovina), short-leaved fescue (F. ovina brevifolia), Wolf false oat (Graphiphorum wolffi), squirrel-tail grass (Hordemum jubatum), little barley (Hor. pusillum), excellent meadow grass (Melica spectabilis), false buffalo grass (Munroa squarrosa), reed meadow grass (Paniculatia americana), nerved needle grass (P. nerrata), old witch grass (Panicum capillare), switch grass (P. virgatum), mountain timothy (Phleum alpinum), timothy (P. pratense), mountain spear grass (Poa alpina), arctic spear grass (P. arctica), Buckey spear grass (B. buckleyana), mountain blue grass (P. cipples), long-stemmed spear grass (P. longipilunculata), Patterson spear grass (P. pattersonii), nodding blue grass (P. reflexa), northern spear grass (P. nemoralis), downy oat grass (Trisetum spiculatum), Texas crab grass (Schedonardus paniculatus), orchard barley (Sitanion brevifolium), western corn grass (Spartina gracilis), drop seed (Sporobolus brevifolius), fine top salt grass (S. arioides), sand drop seed (S. cryptandrus), Canadian needle grass (Sthpia cumbiana), needle grass (S. comata), woolly sedge (Carex longiniosa), Liddon sedge (C. Liddoni, C. ovatina), water sedge (C. aquaticus), giant sedge (C. arisata), black sedge (C. atrata), the beautiful sedge (C. bella), mountain sedge (C. festiva), Hood sedge (C. hoedii), long-beaked sedge (C. longirostris), the new sedge (C. norra), western sedge (C. occidentalis), Raynold sedge (C. raynoldsi), the Nebraska sedge (C. nebraskensis), hillside sedge (C. siecata), alpine or cliff sedge (C. scopulorum), bottle sedge (C. utriculata), variable sedge (C. vari- abilis), spike rush (Elcocharis palustris), small-flowered wood rush (Luzula parviflora), spike wood rush (L. spicata), great bulrush (Scirpus lacustris), small-fruited bulrush (S. microcarpus), Merten rush (Juncus mertensianus), wire grass or Baltic rush (J. balticus), knotted rush (J. nodosus), Rocky Mountain rush (J. saximontanus), Parry rush (J. parryi), alalfa (Medicago sativa), Carolina milk vetch (Astragalus carolinianus), matted clover (Trifolium dasy- phyllum), Parry clover (T. parryi), Hooker sandwort (Arcaria hookeri), winter fat (Eurolia lanata).

In general, the percentage of protein and nitrogen-free extract was found to increase, and that of crude fiber to decrease, with the altitude.

**Electroculture.** T. Griffet (Rev. Gén. Chim., 13 (1910), No. 14, pp. 241-255, figs. 3).—The earlier experiments in electroculture in Europe are briefly reviewed, and the results of recent experiments are reported. Different installations for the purpose of influencing plant growth by means of atmospheric electricity are briefly described. The results seem to indicate that atmospheric electricity is capable of exerting a marked influence in crop production.

**Experiments in electroculture.** Gerlach and G. Erlwein (Elektrochemis. Ztschr., 17 (1910), Nos. 2, pp. 31-36; 3, pp. 66-68, figs. 6).—A description in detail is given of the electrical installation used in these experiments, and the results with barley and potatoes are reported. With both crops the increase in yield was insufficient to defray the expense of the electrical treatment.

**Electroculture.** F. Weis (Tidsskr. Landöökonomi, 1910, No. 2, pp. 136-161).—A résumé of investigations of the subject to date is given, leading to the con-
clusion that electroculture is not as yet far enough advanced to be applied in practical agriculture. It is believed to be more promising in horticulture, especially greenhouse culture, with strawberries, cucumbers, tomatoes, etc., where an advance of about 14 days may secure large net returns. Further investigations, however, are considered necessary to determine whether the installation of the necessary apparatus in greenhouses is remunerative.

A bibliography on the subject is presented.

Report on 25 years' work by the agricultural institution at Rotholz, 1879-1904 (Bericht über die 25 jährige Tätigkeit der Landwirtschaftlichen Landesanstalt Rotholz von ihrer Gründung im Jahre 1879 bis 1904, Innsbruck, 1904, pp. 159, pls. 8, figs. 18, d.gms. 5).—This publication contains a historical review of the institution, outlines the courses given in agriculture, and reports some of the results secured in experimental work, this being based mainly on studies of problems connected with Alpine agriculture.

Report of work with barley, peas, and vetches at Svalöf in 1909, H. Tedin (Sveriges Utsädesför. Tidskr., 20 (1910), No. 4, pp. 245-255; abs. in Bot. Centbl., 116 (1911), No. 6, p. 160).—In a test of 27 2-row barleys 0219 and 0202 Svalöf Gullcorn produced the highest yield. In a test of 12 6-row barleys at Svalöf and Lönstorp Nordschlesowigst Jütte and Tystofte 27 produced the highest yields.

Alfalfa management in Montana, A. Atkinson (Montana Sta. Circ. 5, pp. 72).—Directions for producing alfalfa and alfalfa seed in Montana.

The time of applying potash salts in buckwheat culture, Clausen (Illus. Landc. Ztg., 31 (1911), No. 10, pp. 73, 74, figs. 5).—The results here reported were secured during 2 years of work.

The use of kainit in the spring reduced the yield by about one-half, while its application in the fall was not injurious but was of indifferent value. It was found that kainit as a fertilizer for buckwheat was of value only when applied to the preceding crop in the rotation.

Corn judging, R. J. Nelson (Univ. Ark. Col. Agr., Cir. 1, 1909, pp. 3-7).—This is a circular of information for the members of the boys' corn clubs of Arkansas. A score card for corn and directions for selecting an exhibit of seed corn are followed by notes on the score card and its use.

Corn and cotton, M. Nelson (Univ. Ark. Col. Agr., Cir. 3, 1910, pp. 8).—Methods for producing corn and cotton are briefly outlined.

Experiments with cotton, J. F. Duggar and E. F. Cauthen (Alabama Col. Sta. Bul. 153, pp. 15-40, pls. 4).—Among the cotton varieties tested on plats in 1910 Cook, Dillon, Hardin, and Triumph yielded best; "in observation rows, Bate Early Victor, New Triumph, Excelsior Wilt-Resistant, Triumph from Alabama, and Franklin all yielded well." The earlier varieties were Early Mammoth, Broadwell, Bank Account, Trice, Sugar Loaf King, and Shelley, while Hardin, Dillon, Pounot, and Russell were among the later varieties.

Larger yields followed the use of acid phosphate than were obtained after ground rock phosphate or basic slag. Rowden, Cleveland, Dixie, Simpkins, Dillon, and Pounot were among the varieties least damaged by anthracnose.

Seed treatment reduced the amount of boll-rot or anthracnose. Immersion of seed in water at 170°F. for 10 minutes was followed by a crop having only 4.9 per cent of the bolls diseased as compared with 11.3 per cent from the untreated seed. The crop secured from seed treated for 22 minutes at a temperature of 150°F had 2.4 per cent boll-rot as compared with 9.9 per cent from untreated seed on an adjacent plat. When the seed coat was charred with concentrated sulphuric acid the percentage of diseased bolls was apparently reduced from 11.3 to 5.9. With formalin 4 and 5 per cent, copper sulphate, and carbon bisulphid, the percentages diseased were larger.
At Loachapoka on soil badly infected by wilt or black root, Cook No. 397-6, yielded 3$\frac{3}{5}$ as much lint as the nearest plat of common cotton; Covington-Toole 3$\frac{1}{5}$ times as much; Cook from Hall about 2$\frac{1}{3}$ times as much; Excelsior Wilt-Resistant 2$\frac{1}{10}$ times as much; and a hybrid cotton nearly 2$\frac{1}{2}$ times as much. When wilted plants were carefully dug and thoroughly burned, and the soil for several feet around saturated with formalin (4 oz. to 1 gal. of water) the disease was not again noted, and this treatment is considered advisable when only a few plants are affected.

**Does better cotton seed pay?** M. Nelson (Arkansas Sta. Circ. 8, pp. 4).—Suggestions on the choice of a cotton variety are accompanied by directions for obtaining better seed.

**Fighting the boll weevil**, W. E. Hinds (Alabama Col. Sta. Circ. 6, pp. 7).—This circular calls the attention of cotton growers to the fact that if the cultural methods as outlined are practiced there will be little difficulty in producing increasingly profitable cotton crops in spite of the boll weevil.

**Destroying boll weevils by clean farming**, W. E. Hinds (Alabama Col. Sta. Circ. 7, pp. 8).—This circular outlines methods for combating the boll weevil and directs attention to the fact that if the stalks are destroyed by October 10 each year as good crops of cotton can be made as in the past and that if other improved practices are adopted, as suggested in this series of circulars, the average yield of cotton in the State can be greatly increased in spite of the presence of the boll weevil.

**Flax growing in Montana**, A. Atkinson and D. B. Swingle (Montana Sta. Circ. 6, pp. 9-16).—This circular gives directions for growing and harvesting flax and for combating the wilt disease.

A comparison of nitrate of soda and ammonium sulphate as fertilizers for oats, H. Svorana (Ztschr. Landw. Versuchs., Österr., 13 (1910), No. 10, pp. 812-823).—The experiments here reviewed were carried on cooperatively in 1909 and the results are reported in tabular form.

The yields on the check plats, or those receiving no fertilizers, varied from 770 to 3,240 kg. per hectare of grain, the average being 1,653 kg. (1,471 lbs. per acre), and the corresponding yields for straw were from 1,190 to 3,840 kg., with 2,330 kg. as the average for 9 tests. Plats receiving 500 kg. of superphosphate and 100 kg. of potash salts produced a general average of 1,896 kg. per hectare of grain and 3,364 kg. of straw. On plats which in addition to this application received 145.2 kg. of nitrate of soda per acre, there was an increase of 495 kg. of grain and 942 kg. of straw as compared with the unfertilized plats and of 262 kg. of grain and 508 kg. of straw as compared with the plats receiving superphosphate and 40 per cent potash salt. These results from nitrate of soda were better than those secured from the use of 108 kg. of ammonium sulphate per hectare, but the financial results were in two cases in favor of the use of the sulphate.

**Winter oats for the South**, C. W. Warburton (U. S. Dept. Agr., Farmers' Bul. 436, pp. 32, figs. 9).—The author deals with the comparative value for the South of winter and spring oats, winter oat varieties, their soil, fertilizer, and climatic requirements, and use in rotation. Directions are given for the preparation of the seed and seed bed, sowing the seed, later treatment of the land, and harvesting the crop. Other topics discussed are improvement of the crop, insects and diseases, and the use of the grain, straw, and of the growing crop for pasture and other purposes. Tables state the average acreage, yield, and value of the oat crop and the average acreage and value of oats, corn, and wheat in the Southern States for the 10 years from 1900 to 1909.

**Potatoes**, T. S. Parsons (Wyoming Sta. Bul. 86, pp. 29, figs. 5).—In a test of varieties of potatoes Pierce produced the highest average yield, 260.4 bu. per
acre. In irrigation tests the plats irrigated 3 times produced higher yields than those irrigated 1, 2, or 4 times.

Directions are given for producing, harvesting, and storing the potato crop.

Ramie (Rhea), China grass, H. A. CARTER (London, New York, Melbourne, and Tokyo, 1910, pp. VII+140, pls. 28).—The author discusses varieties of ramie and their soil and climatic requirements. Directions are given for producing the crop, for decortication of the fiber and its preparation for market, and for its manufacture into yarns, cloth, and other articles.

A contribution on the breeding of rape and turnips, A. HUMMEL (Illus. Landw. Ztg., 30 (1910), No. 56, pp. 523-526, figs. 11).—This article embraces discussions of the practical work connected with the breeding of these crops, of the morphological differences of the two plants and their crosses, and of heredity problems in this connection, together with the methods of selection.

The results of experiments in the selection of rape indicate that the number of desirable progeny was greater than the number of undesirable individuals and that on an average the heavier plants produced the more valuable progeny. The author considers that with individual selection the results may be designated arithmetically after the limits of error have been determined and recognized, but that conclusions should not be drawn before the limits of error have been determined, for which from 5 to 6 years of observation are necessary.

The wild rice of tropical Africa, A. CHEVALIER (Jour. Agr. Trop., 11 (1911), No. 115, pp. 1-3).—A general description of this native rice (Oryza barthii) is given, together with a discussion of its value and its culture by the natives. In addition to this its botanical relationships are considered.

Investigations on the influence of climate on the sugar content of the modern highly bred sugar beet, F. STROHMER (Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 39 (1910), No. 6, pp. 919-921, fig. 1).—The author secured in Üholčky a number of mother beets of the same type and variety and grew several of them for seed in the region of the Brenner Pass, 1,050 meters above sea level, allowing the rest of them to produce seed at Üholčky. The following season the seed produced at these two points was compared at Gross-Zinkendorf in Hungary and at Dürakrut in Lower Austria, regions with different climatic conditions.

The results showed that the climatic factor had not influenced the content of sugar, ash, or nitrogenous substances, and, further, that mother beets high in sugar but low in growth, although yielding comparatively small seed balls with a reduced germinating power, are nevertheless capable of producing among their progeny individuals of the best quality. The author, however, advises against the use of such seed for breeding purposes on account of the reduced germination energy, which may at times result in an imperfect stand.

Correlation between weight and sugar content in beets, H. PLAHN (Centbl. Zuckerindus., 19 (1911), No. 18, pp. 572, 573).—In discussing this subject the author points out that some of the beets grown from seed of the same mother plant often show a tendency toward intense growth, while other individuals, although selected on the basis of weight, seem to indicate that an increase in weight of the individual is possible only at the expense of the sugar content.

Observations were made on individuals grown from seed of 50 different plants and it was found that in some instances the average polarization of heavy beets, or those weighing over 1,000 gm., was approximately the same as the average polarization of light beets, or those weighing under 1,000 gm. The author regards this as indicating that where the polarization is about the same, the strains are capable of being increased in weight, while in those instances in which the polarization differs to a perceptible extent the limit of
sugar content has been reached. A table is presented showing the relation between sugar content and weight in different strains, for the purpose of illustrating his views.

Methods of making germination tests of sugar-beet seed. H. Plahn (Bl. Zuckerrübenbau, 18 (1911), No. 3, pp. 38-41).—The author points out the unreliability of the germination test of sugar-beet seed as usually made. He contends that the samples should be graded according to the size of ball, each grade then tested separately, and the results averaged with reference to the percentage each grade represents of the whole sample. The results of testing a sample of seed by the usual and the proposed methods are given in tables for comparison.

Test of treated and untreated beet seed, H. K. Günther (Bl. Zuckerrübenbau, 17 (1910), No. 24, pp. 389-393).—Results reported of experiments with treated and untreated beet seed show that in every instance a beneficial effect on the yield of beets and on the sugar content was observed as apparently due to impregnating the seed balls with certain chemical solutions or in paring down or removing the coat of the seed ball before planting.

Fifteen years' practical experience in beet seed production, H. Schmidt (Bl. Zuckerrübenbau, 17 (1910), Nos. 10, pp. 161-165; 11, pp. 177-181).—This article describes in detail the production of sugar-beet seed and points out the market requirements for it in Germany and Austria. Tables are given showing the required germinating capacity as based on the size of ball and the latitude allowed in making the germination tests.

Tests of 6 varieties of wheat, H. Compain (Ann. École Nat. Agr. Rennes, 3 (1909), pp. 137-154, figs. 6).—In connection with a comparison of the six different varieties the method of clipping the grain when young to prevent a possible lodging was tested. These varieties all made good growth during the winter and were in very vigorous condition at the end of April so that lodging later on was feared. On May 8, the plants on one-half of each plat were clipped, this consisting in removing the extremity of the leaves.

The results showed that in some varieties there was an apparent gain in yield due to clipping, while in others no advantage was discernible and in the case of 2 varieties it proved a disadvantage.

The heating of seeds, E. Miege (Ann. École Nat. Agr. Rennes, 3 (1909), pp. 141-146).—In the experiments reported here, seeds were heated at 30, 45, and 70° C. for 3, 6, 12, and 24 hours.

After 6 hours of heating at 30°, the weight of the seeds had not changed, but after 6 hours of heating at 70°, hull-less barley had lost 0.47 per cent of its weight, hulled oats 0.22, barley 0.35, oats 0.37, wheat 0.47, corn 0.57, and sugar-beet seed and buckwheat 0.14 per cent. After 24 hours of heating the loss in weight in some cases had about doubled.

In general the results of heating did not show a marked advantage. In some cases it was found that as a result of the desiccation the physiological maturity, when the seeds were fresh, was apparently improved.

Weeds and how to eradicate them, T. Shaw (St. Paul, Minn., 1911, 3. ed., rev., pp. 236, pl. 1, figs. 21).—The subject of weeds is treated in a comprehensive manner, individual species are described, and methods for their eradication and control, including the use of sprays are presented. Among the different topics to which chapters are devoted in the book are the injurious effects of weeds, the possibility of their destruction, agencies concerned in their distribution, the methods and principles generally applicable in destroying weeds, the methods of eradicating weeds of the thistle family, the means of destroying weeds of the mustard family, the specific modes of combating the weedy grasses, and the eradication of miscellaneous troublesome plants.
The fruit growers' guidebook, B. H. Favor (St. Joseph, Mo., 1911, pp. 285, figs. 60).—A popular manual of fruit growing intended as a guide for beginners and as a handy reference work for the commercial orchardist. The subject matter is discussed under the headings of the orchard, orchard heating, thinning and harvesting, packing, spraying, orchard pests and diseases, principles of pruning, profits in fruit growing, and small fruits.

Fruit growing at Weraroa Experimental Farm, W. A. Boucher (Jour. New Zeal. Dept. Agr., 2 (1911), No. 3, pp. 143-153).—This consists of notes and tabular data on varieties of orchard and small fruits being tested at the Weraroa Experimental Farm.

Suggestions on commercial muskmelon growing, E. Walker (Arkansas Sta. Circ. 9, pp. 3).—The phases discussed include fertilizers, preparing the land, getting a stand, transplanting melons as related to earliness, hardening off the plants, the use of panes of glass for forcing the seed in the field, varieties, and harvesting.

Spraying cucumbers and cantaloups, T. C. Johnson (Virginia Truck Sta. Bul. 5, pp. 83-100).—Cooperative field experiments for the control of anthracnose and mildew conducted during the summers of 1908 to 1910 inclusive are reported, together with a résumé of experiments conducted at the station in 1910 to determine the relative efficiency of a number of different sprays as a means of controlling these diseases.

In 1908, with 3:6:50 Bordeaux applied 3 times with cucumbers and 4 times with cantaloups, there was a net return for the increased yield of $46.70 per acre for cucumbers. The sprayed portion of the cantaloupe field yielded at the rate of 10,000 melons per acre while the unsprayed portion yielded 3,500 melons per acre, and the sprayed melons sold at an increased value of from 25 to 30 cents per hundred, owing to their better quality.

A similar experiment in the control of anthracnose on cucumbers in a commercial field was made in 1909 in which the object sought was to prolong the bearing period until after the bulk of the crop from earlier plantings had been marketed. The vines sprayed with Bordeaux yielded at the rate of 144\(\frac{1}{2}\) bbls. per acre and the unsprayed vines 169 bbls. The variation in yield became more marked as the picking season advanced. The sprayed vines still bore a fair yield when plowed under on August 2, while the unsprayed vines were dead.

In a similar commercial experiment conducted in 1910, 8 applications of Bordeaux mixture were made, beginning June 18 and at subsequent intervals of a week or 10 days. The increased production resulted in a net gain of $25.56 per acre.

In the station tests there was applied Bordeaux mixture 3:6:50; Sulfocide used first one part with 200, and later with 250, parts of water; self-boiled lime-sulphur 8:8:50; and commercial lime-sulphur at the rate of 1 part to 50, 75, and 100 parts water. The efficiency of the sulphur sprays used at the rates given seemed to be entirely insufficient to justify their further use as a fungicide for this class of plants, and they injured the foliage more or less seriously. As compared with the check plats, Bordeaux mixture increased the yield of cucumbers 59.1 per cent while Sulfocide, self-boiled lime-sulphur, and commercial lime-sulphur caused losses of 11.4, 24.8, and 65.8 per cent, respectively. In the cantaloupe plat Bordeaux mixture increased the yield 11.2 per cent and Sulfocide, self-boiled lime-sulphur, and commercial lime-sulphur reduced the yield 31.3, 23.4, and 70.2 per cent, respectively.
Orchard and garden spraying, A. G. Ruggles and E. C. Stakman (Minnesota St. Bul. 121, pp. 3-32).—The various insecticides and fungicides are discussed in detail and notes are given on the principal diseases of fruits and vegetables with suggestions for their control, notes on spraying machinery, and other data. A spray calendar is included.

Spray and practice outline for fruit growers, 1911, H. J. Eustace and R. H. Pettit (Michigan Sta. Spec. Bul. 54, pp. 20, figs. 7).—This outlines the methods of control for the more common insects and diseases of the apple, peach, pear, plum, cherry, grape, currant, gooseberry, blackberry, dewberry, strawberry, and potato, and gives directions for preparing various fungicides and insecticides.

Spraying the apple orchard, A. Dickens and T. J. Headlee (Kansas Sta. Bul. 174, pp. 253-292, figs. 19).—Demonstration experiments conducted in 1910 cooperatively by the Kansas Station, the United States Department of Agriculture, and the owners of 7 orchards in different localities are described, together with an additional experiment conducted to determine the relative value of Bordeaux and lime-sulphur in preventing apple blight in an orchard hitherto so badly infested as to destroy practically the entire crop. Recommendations relative to number and time of sprays, spraying machinery and materials, and the method of application are also given.

In the demonstration experiments 3:4:50 Bordeaux plus 2 lbs. of lead arsenate was compared with 2 lbs. of lead arsenate plus 1½ gal. of prepared lime-sulphur testing 33° Baumé and 50 gal. of water. In most cases applications of each mixture were applied at the opening of the buds, at the fall of the petals, and 3 weeks later. A fourth application of 2 lbs. of lead arsenate to 50 gal. of water was applied to each lot of sprayed trees 10 weeks after the falling of the petals. The data secured were based on the examination of 256,240 apples and are deemed sufficient to make the results of commercial importance.

**Percentage of total yield of apples injured by, or free from, insect attacks, fungus diseases, and spray injury, in spraying trials.**

The average cost per tree for the Bordeaux-lead-arsenate treatment was 37 cts. and for the lime-sulphur-lead arsenate treatment 40 cts. In general, carefully sprayed trees gave an average of 37 per cent more merchantable fruit as compared with untreated parts of the same orchard. The first 2 grades of fruit were increased 15 per cent and 6.6 per cent, respectively. When sold as "orchard run" the average net increased value from the sprayed fruit was $97.20 per acre.

Both lime-sulphur and Bordeaux checked apple blight materially in the orchard badly infested, the Bordeaux being more effective when apple blight alone considered. Three sprayings proved better than 2. Arsenate of lead was used with both sprays in the first 2 applications. It was found that whereas
the trees injured by Bordeaux produce about as much merchantable fruit as those injured by lime-sulphur, they produce less first grade and more second grade fruit than the latter. One variety, the Ingram, was practically free from Bordeaux injury. In general, prepared lime-sulphur plus lead arsenate produced the best results on apples which are subject to Bordeaux injury and are nearly free from apple blotch, while Bordeaux-arsenate of lead gave the best results on varieties subject to apple blotch.

How to control the scab and blotch of the apple, J. L. Hewitt (Arkansas Sta. Circ. 7, pp. 4).—This is a popular discussion of the general characters and methods of dissemination of apple scab and apple blotch, together with directions for summer spraying of orchards that are infested with these diseases, codling moth, and curculio. The treatment recommended consists of 5 applications of Bordeaux mixture, the second, third, and fourth containing 2 lbs. of arsenate of lead to every 50 gal. of the spray. Lime-sulphur may be substituted in the first 3 sprayings.

Self-boiled lime-sulphur wash and its use, P. F. Williams and J. C. C. Price (Alabama Col. Stn. Bul. 152, pp. 12, pls. 3, figs. 3).—Descriptions are given of brown rot (Sclerotinia fructigena), peach scab (Cladosporium carpophiliun), and plum curculio, together with directions for the preparation and application of the self-boiled lime-sulphur mixture and of arsenate of lead for combating these pests.

The results of experiments with lime-sulphur on apples and peaches at Auburn, Ala., are also reported. In the apple orchards 98 per cent of perfect fruit was obtained by 3 sprayings, the first a 2:3:5 arsenate of lead spray for the codling moth, and the other two consisting of 8:8:50 self-boiled lime-sulphur mixture for the black and bitter rots.

In the experiments with Carman, Elberta, and McKinnel peaches the respective percentages of perfect fruit were with spraying 97.6, 92, and 89, and without spraying 48.6, 75, and 0. An orchard of 1,500 peach seedlings left unsprayed during the season of 1909-10 showed only a 2 per cent resistance to brown rot. It is claimed that in the work with peaches and apples much of the success with summer treatment depends upon previous pruning and thorough winter spraying with the concentrated lime-sulphur.

The reserve materials of the vine, J. L. Vidal (Rev. Vit., 35 (1911), Nos. 895, pp. 157-162; 896, pp. 189-195; 897, pp. 219-222; 900, pp. 307-312; 903, pp. 390-395, figs. 6).—The author finds from a study of the carbohydrates in vines that the root is the reserve organ and that there is a double annual migration of reserve materials. A portion of the reserve materials flows upward in the spring with increasing rapidity until the young leaves begin to function, when the flow decreases and the materials assimilated by the leaves soon begin to migrate to the shoots, trunk, and roots. The maximum reserve in the shoots is reached just before leaf fall and is immediately followed by a sudden retreat of a part of the reserves to the roots, after which the vine enters into the winter rest period, which the author terms the period of "inversion." Grafted vines comport themselves in a way more or less similar to vines growing on their own roots, depending upon the degree of affinity between stock and scion.

The various practices of pruning are grouped into two classes, according to their time of application—those which are conducted during the period of "inversion" and those which are conducted at other times of the year. Pruning during the "inversion" period appears to be more favorable to the vegetation as well as to the quality and quantity of the products of feeble and normal vines and in conjunction with proper treatment, such as the lengthening of the fruiting wood, reduction of manure, etc., of vigorous vines also. Severe pruning during the "inversion" period combined with repl Pruning just before the buds
open may perhaps retard the vines and protect them from late frost. Pruning during the "inversion" period is better for the plants producing propagating wood, and should be practiced, contrary to the general rule, on stock intended to be grafted in place in spring. On the other hand, pruning during the "inversion" period is not so well suited for the gathering of cuttings and scions. Very early pruning or very late pruning impoverishes the plants of the reserve materials and diminishes their vigor in proportion as the pruning is remote from the "inversion" period. On the other hand, it is efficacious against excessive vegetation and is the best for the taking of cuttings and scions.

Preparing citrus fruits for market, W. C. Temple (Fla. Grower, 3 (1911), No. 32, pp. 3-6, figs. 7).—This article deals with harvesting and packing-house methods, including illustrations of first-class packing-house equipment.

Home floriculture, C. N. Page (Des Moines, Iowa, 1911, pp. 173, figs. 48).—A popular guide for the growing of flowers in the house and garden, including suggestions on cut-flower work, garden design, etc.

The gladiolus, M. Crawford (Chicago and New York, 1911, pp. 98, pls. 7, figs. 2).—A practical treatise on the culture of the gladiolus, with notes on its history, storage, diseases, etc. An appendix by W. van Fleet deals with the garden history of the gladiolus, hybridizing gladiolus, and special care of seedlings, together with brief notes on gladiolus species.

FORESTRY.

The taxation of forest lands in Wisconsin, A. K. Chittenden and H. Irion (Madison, Wis., 1911, pp. 80).—The results are given of a study of forest conditions in Wisconsin conducted cooperatively by the Wisconsin State Board of Forestry and the Forest Service of the United States Department of Agriculture in April, 1910.

The main purpose of the study was to determine the extent of the burden now carried by timber lands as a result of the present methods of taxation and what influence, if any, such methods of taxation have or will have on the practice of forestry by private owners. Ten counties considered typical of the northern part of the State were selected for detailed study. In addition as much information as possible was collected in the other counties of the State. A general description is given of the area specially studied relative to the character of the land and timber, cut-over lands, settlement, agricultural development, annual cut, and importance of the lumber industry. A summary is given of assessed values compared with actual values and a few typical examples of actual taxation are further discussed, together with the methods of assessing timber lands, views of lumbermen on taxation, the attitude toward fire, tree belt, and forest plantation laws, tax laws in other States, and probable returns from forest investment.

The general conclusion relative to the taxation of forest lands is that the present method of assessing forest lands is exceedingly uneven and in many cases unfair to the timber-land owner. Recommendations are made for the formulation and application of a remedy, the proposed solutions being discussed under the headings of wood lots limited in area and private forests without any limitation as to area. It is pointed out that even with the adjustment of the
tax laws, the development of forestry by private capital is not apt to be extensive enough to furnish a sufficient supply of timber in the future.

An article by F. R. Fairchild on the economic problem of forest taxation is appended almost in full.

Shall States regulate the management of private forests? H. H. CHAPMAN (Amer. Forestry, 17 (1911), No. 2, pp. 82-88, pls. 2).—An examination of the principles of state regulation with special reference to the control of private forests.

The author recommends the encouragement of private forestry through the dissemination of forestry propaganda, the establishment of demonstration forests, and improving the systems of fire protection and forest taxation. He also advocates the state ownership and control of lands most in need of a perpetual forest and a reasonable degree of regulation of lands where the indirect influence of the forest on streams and erosion is clearly proved.

The National Forest manual.—Special uses (U. S. Dept. Agr., Forest Serv., 1911, pp. 35).—This manual, which constitutes a part of the Use Book (E. S. R., 24, p. 548), consists of regulations of the Secretary of Agriculture and instructions to forest officers relating to and governing special uses of the National Forest lands.

Fifth annual report of the Forest Park Reservation Commission of New Jersey for the year ending October 31, 1909 (Ann. Rpt. Forest Park Reserv. Com. N. J., 5 (1909), pp. 56, pls. 5).—This report deals chiefly with the question of forest fires. A summary is given of forest fires in 1909, violations of the law, and the cost of the fire service, together with a discussion of fires in other States, railroad fires, the forest fire service, state forest reserves, educational work, forest planting, shade trees, tree enemies, the needs of the state forest service, and a financial statement for the year.

[Forestry in North Carolina], J. H. PRATT and J. S. HOLMES (N. C. Geol. Survey, Bien. Rpt. 1909-10, pp. 53-105).—This consists of a progress report on operations along various lines of forestry conducted by the North Carolina Geological and Economic Survey during the fiscal years 1909 and 1910. The work under way consists of an investigation of the forest conditions of North Carolina, studies of forest fires and of the wood-using industries of the State, the examination of timber areas in regard to practicing scientific forestry, the examination of watersheds belonging to municipalities as to their protection against fire and contamination, and investigations regarding the reforestation of abandoned farm lands and cut-over lands.

Forestry in Russia, L. S. WOOD (Quart. Jour. Forestry, 5 (1911), No. 2, pp. 101-119).—This consists of a report on the examination of about 309,951 acres of timber land in the Province of Perm, Russia, including data relative to the nature of the stands and growth measurements of sample areas and trees.

The climatic differences upon northern and southern slopes in their relation to the water content of clean-cut and forest-covered soils, R. WALLENHÖCK (Centbl. Gesam. Forstw., 37 (1911), No. 2, pp. 51-63).—The results are given of soil moisture determinations made in the years 1909 and 1910 on clean-cut areas and on soils covered with mature beech stands, both on northern and on southern exposures. The season of 1909 was classed as a dry season and 1910 as a wet season.

The results secured from the determinations as a whole show that the water content of the soils is greater on clean-cut areas than on beech stands, both on northern and southern slopes and in dry and wet years. In wet years the clean-cut areas take up more moisture on southern slopes and less moisture on northern slopes than mature beech stands on the corresponding slopes. The difference in water content of the cleared areas and the forest soils is greater
on the sunny slope during a wet season and greater on the shady slope during a dry season. The difference in water content of the variously exposed cleared areas is greater in dry years and less in wet years than the variously exposed forest areas.

The experimental work reported is preceded by a general discussion relative to the modification through forests and exposure of the climatic elements affecting soil moisture.

A critical discussion of forest manuring experiments, P. Ehrenberg (Ztschr. Forst u. Jagdwr., 43 (1911), No. 3, pp. 174—202).—A critical inspection of the present methods of conducting fertilizer experiments with young trees and with mature stands, both from the theoretical and scientific points of view.

The utilization of machinery in the culture of pines with special reference to the sowing of pine seed in plowed furrows with the aid of a fertilizer distributor and forest seed planter, Schenk von Schmitthure (Allg. Forst u. Jg. Ztg., 87 (1911), pp. 58-63; pp. 77-81, fig. 1).—The author points out the difficulty of securing sufficient and capable laborers for the work of establishing pine stands as the principal necessity for the utilization of machinery for this purpose. His practice of sowing pine seed in plowed furrows and subsequent cultivation between the rows is here compared with the usual method of sowing pine seed broadcast. A fertilizer distributor and seed planter devised by the author to plant forest seed is illustrated and described, and detailed estimates are given of the cost of sowing and maintaining for the first four years 1-hectare plantations set out or seeded by hand and seeded with the seed planter.

Harvesting the annual seed crop, S. Moore (Amcr. Forestry, 17 (1911), No. 3, pp. 153-154, pls. 4).—The conditions and work of harvesting the forest-tree seed crop described in this article are deemed particularly typical of the Rocky Mountain region and the work as carried on by the Forest Service of the United States Department of Agriculture upon the National Forests of that region.

The growth and management of Douglas fir in the Pacific Northwest, T. T. Munger (U. S. Dept. Agr., Forest Serv, Circ. 175, pp. 27, figs. 4).—The purpose of this circular is to show how a new crop of timber can be started on logged-off land, the conditions favorable to its development, its rate of growth and yield, and the probable cost of securing the second crop. The Douglas fir, which is selected as the most abundant and most important commercial tree of the Pacific Northwest, is discussed relative to its important characteristics, including soil and climatic requirements, density of stand, susceptibility to injury by fire, fungi, and insects, reproduction, rate of growth, and management of second growth stands, including provisions for a second crop, yields, costs, and profits. The appendix contains tabular data showing the cubic and merchantable contents, as well as the number of hewed railroad ties and round mine timbers obtainable from trees of different diameters.

The general conclusion is reached that Douglas fir is the best all-round timber tree for the Pacific Northwest and that reforestation can be attained at little expense after any Douglas fir logging operation by making provision for seed trees to seed up the areas; burning the slashing immediately after logging; and protecting the cut-over area from subsequent fires. By observing these measures the growth of the second crop will be as rapid and the quality as good as the original forest. “That the growing of crops of Douglas fir on cut-over land will be financially profitable to private owners seems assured in view of the certain rise in the valuation of stumpage, the growing security of timberland investments, and the increased market for young timber, provided only
that the system of taxing timberlands is reformed so that such lands bear only their just share of taxation."

Trees of the Tasmanian forests of the order Myrtaceae: The genus Eucalyptus, L. ROWEY (Agr. and Stock Dept. Tasmania Bul. 17, 1910, pp. 15).—This consists of a general account of the genus Eucalyptus, together with botanical descriptions of the various Tasmanian eucalypts and additional notes on the general appearance of the more common forms in the forest.

The tree species of Java: Contribution No. 12, S. H. KOORDERS and T. VALETON (Meded. Dept. Landb. [Dutch East Indies], 1910, No. 10, pp. VI+782).—This is the twelfth of a series of reports on the tree species of Java which have been published from time to time and the first of which appeared in 1894.

The present report gives the contents of the previous volumes and deals specifically with the species and genera of Buxaceae, Euphorbiaceae, Ulmaceae, and Urticaceae. In addition to full botanical descriptions the information under each species includes references to literature and notes on the geographical distribution, uses, and native names of the trees.

The virgin forests of Kamerun, JENTSCH (Tropenpflanzer, Beihefte, 12 (1911), No. 1–2, pp. IV+199, pls. 6, figs. 11).—During 1908–9 the author in conjunction with Prof. Blisgen made a survey of the forests of certain sections of Kamerun and Togo. A general account of this trip, dealing with the forest conditions, possibilities, and botany has been previously noted (E. S. R., 21, p. 741). The present report embodies the results of investigations made relative to the composition and character of the areas examined, and gives the author’s conclusions relative to the utilization and conservative exploitation of the forests, together with considerable information of value in the establishment of private wood-using industries.

The appendixes contain tabular data on sample areas examined, growth measurements and descriptions of a number of species relative to their technical application, estimates relative to the cost of establishing wood industries, and soil analyses.

A study of the wood-using industries of Kentucky, R. E. SIMMONS ((1910), pp. 74, pls. 11).—The results are given of a statistical study, conducted cooperatively by the Forest Service of the United States Department of Agriculture and the State of Kentucky, of the industries of that State which use wood in the manufacture of finished products. The tabular data given and discussed show the source of each of the woods used by the manufacturers, whether grown in Kentucky or elsewhere, the quantity used, prices paid delivered, uses to which the various species are put in making the commodities or portions of commodities, and the extent of the field over which products are distributed.

The total estimated quantity of wood consumed by the Kentucky manufacturers making products in form ready for the ultimate consumer is 780,141,800 ft. b. m., costing delivered at the factory $15,160,574.

Wooden and fiber boxes, H. MAXWELL and H. S. SACKETT (U. S. Dept. Agr., Forest Serv. Cir. 177, pp. 14).—This circular embraces the results of an investigation conducted to determine to what extent the fiber box has replaced the wooden one, how far the development of the fiber box industry is likely to go, and what effect, if any, the growing use of fiber boxes will have in bringing about the fullest utilization of forest-grown material. Both industries are discussed relative to their nature, extent, and rival claims of merit.

The two kinds of boxes as compared show in general that the cheapness of fiber is the most stubborn factor in the competition with wood, but that this competition is active only for rather small boxes and for those for which extra strength is not demanded. The prospect seems good that material for both kinds
will be adequate to meet the demand for many years and that the majority of shipping boxes will continue to be made of wood. The wood waste at sawmills and in the forests is suggested as material for fiber making, practically the only difficulty in its use being the fact that such waste is scattered and the cost of collecting it may be considerable.

Rubber: Production and utilization of the raw product, C. Beadle and H. P. Stevens (London, Bath, and New York [1910], pp. X+132, pl. 1, figs. 39).—A popular work intended as an introduction to the study of rubber and dealing both with the production of the raw material and the subsequent manufacturing processes.

**DISEASES OF PLANTS.**

Methods of keeping bacteria from growing plants, J. K. Wilson and H. A. Harding (._Abs. in Science, n. ser.,_ 33 (1911), No. 849, p. 545)._—The method suggested is the growing of plants in sterile Mason jars, using sterilized seed and soil wherein exchange of gases is provided for by soldering a ½-inch tube into the metal jar top, plugging the tube with cotton, and covering it with an inverted test tube to reduce the chances of contamination and check evaporation. Alfalfa plants in such jars in sterilized sandy soil, to which 10 per cent of water had been added, grew thriftily during 4 months without being watered or the jars opened.

Investigations on the dissemination of microscopic spores in the atmosphere, G. Bonnier, L. Matruchoit, and R. Combès (Comp. Rend. Acad. Sci. [Paris], 152 (1911), No. 11, pp. 652-669, fig. 1)._—By a suitable apparatus, which is figured and described, the author determines the number of spores in a given volume of air (50 liters), as shown by plate colonies.

The influence of the culture media on the growth of the organisms and that of vegetation and of altitude on the dissemination of spores were investigated. It was found that the kind of culture media used had a very appreciable influence on the number of colonies of a given species that would show on the plates. The air from dense forests showed more fungi and bacteria than that from open places. The higher the altitude the fewer the colonies, until at a height of 2,190 meters only 64 colonies of fungi and none of bacteria were obtained.

In every instance the number of colonies of fungi were far in excess of the bacterial colonies. For instance, in forests there were 3,260 colonies of fungi and only 13 of bacteria.

New or rare species of fungi in the environs of Palermo, G. E. Mattei (Bot. R. Orto Bot. Palermo, 9 (1910), No. 1-3, pp. 149-144)._—Of 23 fungi noted, 13 are described as new by Saccardo, viz., _Ascochyta sēmeces_ on the leaves of _Semele androgynae_; _Asteroma antholyza_ on the leaves of _Antholyza bicolor_; _Asteroma caramoides_ on the dead stems of _Smyrnium olusatrum_; _Gloeosporium aniceps_ on the leaves of _Arbutus unedo_; _G. criniti_ on the dying leaves of Crinum in company with _Phylosticta criniti_; _G. ocandri_ on the leaves of _Nerium oleander_; _Marsonia matelliana_ on the dying leaves of _Quercus robur_; _Penicillium coccophilum_ on the shields of _Ceroplastes rusi_, adhering to the branches of _Ficus capensis_ and parasitized by _Thoracantha cyanea_; _Phylosticta criniti_ on the dying leaves of Crinum; _P. paratropic_ on the living leaves of _Paratropic rotundifolia_; _Septoria cirrosa_ on the dying leaves of _Clematis cirrosa_; _S. dryophila_ on the leaves of _Quercus ilex_ and _Stilbum coccophilum_ on the shields of _Ceroplastes rusi_, adhering to the branches of _F. capensis_ and parasitized by _Thoracantha cyanea_.

A method of developing _Claviceps_, H. H. Whetzel and D. Reddick (Phytopathology, 1 (1911), No. 2, pp. 50-52, pl. 1)._—The authors report the successful development of stromata from the sclerotia of _C. purpurea_, which in August had
been inclosed in a screen wire and put on the ground under a grape vine until April of the next year, then carried into the laboratory and placed in moist sand in a covered sticker dish.

The smuts of grain crops, E. M. Freeman and E. C. Stakman (Minnesota Sta. Bul. 122, pp. 35-64, figs. 11).—This is a general discussion of the life histories of the common smuts of grain in Minnesota and of methods of treating each. The smuts discussed are corn smut, oat smut, stinking smut of wheat, covered smut of barley, sorghum grain smut, and loose smut of wheat and of barley. Directions are given for using the formalin, copper sulphate, and hot-water treatments.

Studies of the life history of the head smut of sorghum, A. A. Potter (Science, n. ser., 33 (1911), No. 849, p. 551).—In a paper read before the Botanical Society of Washington March 7, 1911, the author presented the results of his investigations on the life history of this smut.

Attempts to prevent this smut by seed treatment have failed. Numerous inoculation experiments are reported, but neither local infection, seedling infection, nor floral infection was demonstrated. Detailed histological study has shown that the host plant is affected as a whole, and therefore that the infection must take place at an early stage in the growth of the host. Peculiar floral alterations were shown to be caused by the smut and to contain the smut mycelium, from which it is suggested that the smut may be hereditary, as is the fungus of certain species of Lolium.

Infection experiments with legumes, K. Brux (Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 9 (1911), No. 3, pp. 35-41, figs. 2).—The results of infection experiments with red clover and serradella are reported. The yield of green matter on the inoculated areas showed a marked increase over similar un inoculated plats.

Studies in disinfection of alfalfa seeds, J. K. Wilson (Abs. in Science, n. ser., 33 (1911), No. 849, pp. 544, 545).—The results are given of sterilizing experiments with alfalfa seeds, in which 70 per cent alcohol, 1:1,000 corrosive sublimate, 10 per cent formaldehyde, 95 per cent alcohol for 10 minutes and then followed by 10 per cent formaldehyde, and a vacuum chamber treatment in water followed by 10 per cent formaldehyde, were tried.

None of these completely sterilized the seed except the 95 per cent alcohol 10-minute treatment followed by a 6-hour soaking in 10 per cent formaldehyde, and the germination of the seeds was reduced 65 per cent by this treatment. In the water-vacuum-formaldehyde treatment, pressure 3 mm., time 210 minutes, followed by a 30-minute soaking in 10 per cent formaldehyde, some of the seed were sterilized, but their germinating power was destroyed, from which the author concludes that the air in the seeds probably prevented the entrance of the disinfecting solutions thereby protecting the bacteria.

A contribution to our knowledge of the morphology and life history of Puccinia malvacearum, J. J. Taubenhaus (Phytopathology, 1 (1911), No. 2, pp. 55-62, pls. 3).—In a general study of the life history of this fungus, 2 common types of sporidial formation were observed, first, from free cells formed by the breaking up of the promycelium, and second, the normal sporidia formed on the stergimata. This fungus winters over as (1) living mycelium, as late fall infections develop through the winter and mature their spores in the spring. (2) hibernating telentospores on old twigs or dead leaves, and (3) on the seeds or bracts, but not in the embryo.

Disease-resisting potatoes, G. M. Taylor (Gard. Chron., 3. ser., 49 (1911), No. 1265, p. 181).—In searching for an immune variety of a cultivated potato to be used for breeding disease-resistant strains, the author found in Scotland a potato which had been grown by one family since 1745 and was said never
to have been attacked by disease. This variety has been subjected to severe tests as to disease resistance for the past 10 years, but has never shown any signs of disease. It produced no pollen until 1910, and was also sterile to all pollen of other varieties, but by using its pollen on the varieties Factor and Admiral, fertilization occurred and an abundance of good seed was obtained. This immune variety is of excellent edible quality, and although the color of its tubers and its low yield make it worthless as a commercial potato, its progeny should develop some very valuable disease-resistant strains.

The potato eelworm. S. B. Doten and P. Frandsen (Nevada Sta. Bul. 76, pp. 7, figs. 2).—This bulletin gives a popular discussion of the characteristics of this pest, the damage done by it, and methods of control.

The potato eelworm, S. B. Doten and P. Frandsen, tracts, by Marie Thosi (Nevada Sta. Bul. 76, pp. 7, figs. 2).—An Italian edition of the above.

On the presence of Tilletia horrida in rice flour, P. Filter (Centbl. Bakter. [etc.], 2. Abt., 29 (1911), No. 12-14, pp. 332–346, figs. 4).—Attention is called to the frequent presence of spores of this smut in rice flour, indicating a more general distribution of this fungus than hitherto supposed. According to the author, T. corona is only a synonym of T. horrida.

A new myxomycete on sugar beets, B. Neméc (Ber. Deut. Bot. Gesells., 29 (1911), No. 2, pp. 48–50).—The author describes as new a chytridiaceous para-site which is found in the cortical cells of the side roots of the sugar beet. It does not produce hypertrophy of the attacked cells.

He proposes Sorophidium beta n. g. and sp. as the name of this organism.

Root tumors of sugar beet (Jour. Bd. Agr. [London], 17 (1911), No. 10, pp. 830, 831, pl. 1).—Attention is called to the occurrence in England of tumors on the crowns of the sugar beet, a disease which has long been prevalent in many beet-growing regions on the Continent.

Experiments on the control of Phytophthora on tobacco, H. Jensen (Jaarb. Dept. Landb. Nederland, Indië, 1909, pp. 192–197).—The results are given of experiments with lime and ammonium sulphate, nitrate of soda, carbon bisulphid, formalin, and potassium permanganate in combating the Phytophthora. It was found that both carbon bisulphid and potassium permanganate appreciably checked the Phytophthora without injury to the tobacco plants.

Injury caused by the apple powdery mildew, W. H. Volck (Better Fruit, 5 (1911), Nos. 8, pp. 39–46, 59–61, figs. 9; 9, pp. 60–69).—In a general discussion of the characters of this disease, the damage caused by it, and methods used for its control, the author gives the results of a series of experiments with various fungicides in combating this mildew under California conditions.

The following substances were used as winter sprays in an attempt to kill the fungus on the mildewed twigs: Copper sulphate, Bordeaux mixture, sulphuric acid, iron sulphate and sulphuric acid, lime-sulphur solution, lime-sulphur and salt, lye-sulphur solution, potash and soda-lye sulphids and excess of lye, and lime-sulphur solution and copper sulphate. Pruning off infected twigs was also tried as a remedy. Treatments during the growing season, both curative and preventive, were also tried, as follows: Bordeaux mixture, copper sulphate, ammoniacal copper carbonate, copper acetate, copper carbonate, copper benzoate, copper hydroxid, copper sulphid, metallic copper, copper sulphid plus sulphur, iron sulphid, iron sulphid plus sulphur, sulphur (in various forms), sulphuric acid, lime-sulphur solution, lime-sulphur solution plus barium carbonate, potassium sulphid, benzoates (sodium, ammonium, potassium), salicylates (same as benzoates), picric acid, phenol, potassium permanganate, zinc oxide, zinc arsenite, kedzie mixture, arsenate of lead, and pruning.

The wintering-over fungus upon mildewed twigs was so resistant that none of the fungicides killed it, except in the case of the 10 per cent sulphuric acid
solution, when the fungus was destroyed because the spray killed all the twigs on the tree, both diseased and healthy. Of the summer sprays used, iron sulphid was the only one giving any promise of controlling the mildew under the conditions as found in the Pajaro Valley. The first iron sulphid spraying for mildew should be applied along with the calyx-cup spraying for the codling moth, and, of course, will contain arsenate of lead; this requires that the sulphid precipitate should be carefully washed to free it from soluble sulphur. For this spraying, 10 lbs. of iron sulphate precipitated with lime-sulphur solution should make 100 gal. of spray, to which 6 lbs. of arsenate of lead is added. The second, as well as subsequent applications, should come after a 3-week interval, and consists of 7 lbs. of copperas precipitated with lime-sulphur solution and then diluted with 100 gal. of water. The third and fourth applications consist of 5 lbs. of copper sulphate and 4 lbs. of lead arsenate to 100 gal. of water. It is stated that this iron sulphid treatment will effect a practical control of the mildew under the existing conditions.

It was found that when trees were sprayed with sulphur solutions they acquired an immunity to sulphur injury if sprayed regularly, while a first and a fourth spraying consisting of some form of sulphur mixture often caused serious loss of foliage, and even fruit from the last spraying. Similar trees given 4 successive applications of the sulphur mixtures at intervals of 3 weeks showed no signs of sulphur injury.

The occurrence of apple blotch in Ohio, W. O. Gloyer (Ohio Nat., 11 (1911), No. 6, pp. 334–336, fig. 1).—Attention is called to the presence of this fungus on the Baldwin, Ben Davis, Stark, Pippin, Smith Cider, and Rome Beauty in several counties in Ohio. In one orchard of Pippins 90 per cent of the fruit was blotted, a condition which was not uncommon with many of the varieties named. The disease appeared on sprayed as well as on unsprayed trees, and was due, it is claimed, to a lack of proper pruning, thereby permitting successive crops of spores to be produced on foliage and fruit not reached by the spray.

A summary of various spraying experiments, O. S. Watkins (Kiamundy, Ill., 1911, pp. 16).—In this paper, read before the Fifty-fifth Annual Convention of the Illinois State Horticultural Society at Urbana, Ill., February, 1911, the author gives the results of spraying experiments with various fungicides and insecticides conducted during the summer of 1910 in different parts of the State of Illinois.

Two lines of experiments are reported, one being demonstration experiments designed to show the value of known fungicides and tried methods in renovating old orchards, etc., and the other consisting of detailed experiments intended to answer questions as to the comparative value of different sprays, the use of trade compounds, etc. In the demonstration experiment plats, all the fruit was killed at the time of the second spraying by a severe cold wave. Of the orchards used in the detailed experiments, all had their fruit killed by the cold wave, except the orchard at Neoga which comprised 30 15-year-old Ben Davis apple trees and 12 Grimes Golden trees. Bordeaux mixture, lime-sulphur mixtures, copper ferrocyanide, several proprietary fungicides, different brands of arsenical compounds, and black leaf "40," a tobacco decoction, were tested. Chemical analyses of some 13 proprietary arsenical compounds and commercial lime-sulphur mixtures, and tabulated data as to the tests of these various fungicides and insecticides on both fruit and foliage, are given.

The author concludes that self-boiled lime-sulphur possesses very little fungicidal value in controlling apple scab and is not very adhesive, but was more effective in controlling the scab and less injurious to the foliage than commercial lime-sulphur mixtures. It is claimed that one application of a 4:4:50
Bordeaux mixture proved more effective than 3 applications of lime-sulphur in controlling the scab. Arsenates of lead containing high amounts of arsenic acid, when combined with lime-sulphur, caused more injury to the fruit and foliage than arsenates with a low acid content. The combined action of Bordeaux mixture and milk of lime acted as a shield against the severe freeze of that year.

The use of dilute lime-sulphur for the control of apple diseases, W. M. Scott (Kinnmundy, Ill., 1911, pp. 8).—In this paper, read before the Fifty-fifth Annual Convention of the Illinois State Horticultural Society at Urbana, Ill., February, 1911, the author briefly reviews the status of lime-sulphur as a fungicide for the control of apple diseases, and gives the results of experiments conducted in Virginia during 1910 with lime-sulphur sprays. In these experiments 4 applications of each of the following sprays, viz. 1:5:50 commercial lime-sulphur, 2:4:50 home-boiled lime-sulphur, and 3:4:50 Bordeaux mixture, were tested on Winesap, York Imperial, and Ben Davis apples. Two lbs. of arsenate of lead was added to every 50 gal. of the spray used.

The evidence obtained from these and other experiments conducted by the United States Department of Agriculture and by several of the experiment stations, as well as the work of the orchardists, seemed to warrant the following conclusions: Lime-sulphur solution containing 4 lbs. of sulphur to 50 gal. of spray is a good substitute for Bordeaux mixture in the treatment of apple scab, fruit spot, leaf spot, and cedar rust, but is not satisfactory in controlling bitter rot. When necessary to spray for bitter rot the early applications of lime-sulphur for scab may be followed at the proper time with Bordeaux mixture for bitter rot, thus avoiding the russet and yet controlling the rot.

The cherry in Lower Burgundy.—V, Diseases of cherries, P. Larue (Prog. Agr. et Vit. (Ed. l'Est-Centre), 32 (1911), No. 14, pp. 328-347, fig. 1).—The author gives a key to the diseases of the cherry, in which the symptoms, the name of the parasite (animal or plant), the group to which the parasite belongs, and the method of control are very briefly noted. The diseases of the leaves are treated first, then the damages done by insects to early buds, and then the diseases of the young shoots, of mature branches, and of the trunk, roots, flowers, and fruit.

Crown swelling disease of peach, J. B. S. Norton (Phytopathology, 1 (1911), No. 2, pp. 53, 54).—Attention is called to a serious disease of peach orchards in Maryland which is causing the death of many young trees planted in the spring of 1908 or in the fall of 1907.

In 1909 many of the trees were either dying as if from starvation, or were already dead, having broken off about 2 inches under the ground. An examination of the trees showed but slight connection between the lateral roots and the main root and stem, while there was a distinct swelling at the base of the stem extending upward from 4 to 8 in. A cross section of the tumor showed a spongy layer just beneath the bark of varying thicknesses, composed of parenchymatous cells filled with starch and frequently interspersed with thin woody layers. The large size of the cells, the abundance of starch, and the absence of medullary rays easily distinguished the diseased tissue from healthy wood. The lateral roots seemed to be in the process of being cut off in a way similar to that in which the twigs of willow, poplar, etc., are often shed.

No causative organism was found in the sections, nor in the attempted cultures.

Observations on the California vine disease, O. Butler (Mem. Torrey Bot. Club, 14 (1910), No. 2, pp. 111-153, pls. 5, fig. 1).—The author gives the history of this disease, its symptoms, the histology of infected parts, the rela-
tionship of the disease to similar diseases such as folletage, rogueit, sun scald, brunissure, shelling, and tetanychosis, and the nature of the disease.

As a result of these investigations the conclusion is drawn that the California vine disease is not of parasitic origin, but is due to some weakness in the functions of absorption and translocation of water which becomes manifest when conditions favoring transpiration are marked.

A new enemy of grapes, E. Hain (Umschau, 15 (1911), No. 14, pp. 290, 291, fig. 1).—Attention is called to the occurrence of Lathraea clandestina on the roots of grapevines, where it produces galls at the point of attachment to its host. The immediate uprooting and destruction of the grapevine on the first appearance of this parasite is advised.

On a bacteriosis of the tomato, G. L. Pavarino (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 20 (1911), I, No. 5, pp. 355-358).—Attention is called to a bacterial disease of tomatoes occurring in Italy, which not only produced a rotting of the fruit but caused the buds and young branches to become twisted and curled, while on the larger branches and stems narrow depressed, brownish, cankered areas developed.

After comparing the characteristics of the causative organism with those of Bacterium solanacearum, which produces a similar bacterial rot of tomatoes, the author concludes that the Italian disease is caused by a new species, for which the name B. brisiosii is proposed.

Some diseases of the banana (Agr. News [Barbados], 10 (1911), No. 233, pp. 110, 111).—This is a discussion of the Panama disease and similar diseases of the banana in Costa Rica, Panama, Cuba, Trinidad, and Surinam, in which their symptoms and the causes proposed by different investigators are given.

In Costa Rica and Panama the Panama disease is attributed by some investigators to either a fungus or bacterial origin, while in Cuba a similar disease showed the presence of a species of Fusarium in the discolored vascular bundles. In Trinidad 2 stem diseases (moko and Panama) and a root disease (Marasmius) are noted. In Surinam the Panama disease has been very destructive, especially to the Gros Michel variety of bananas. In a recent letter by Essed to the Imperial Department of Agriculture of the West Indies the Panama disease is attributed to the attacks of a fungus named by him Ustilaginoidea musaeperda, related to the genus Ustilaginoidea which is one of the Hypocreales.

A bacterial disease of bananas and plantains, J. B. Rorer (Phytology, 1 (1911), No. 2, pp. 45-49, pls. 4).—The author describes a bacterial disease of bananas, which was originally discovered on the "moko" fig, a variety of plantain, but which has since been found generally in Trinidad on the Creole and French varieties of plantain, and on the Cavendish banana (Musa chinenisis). The disease first affects the lower leaves, causing them to droop and have a slightly yellowish tinge. Soon the petioles give way just at the base of the leaf blade, while eventually the terminal leaf also bends over, and the plant dies and rots down to the ground. Transverse sections of the pseudostem show that practically all the vessels are discolored and filled with bacteria. These yellow, dark brown, or blue-black, discolored bundles run back into the tree stem, and thence into the young suckers and buds.

The organism was isolated and the disease reproduced by inoculating healthy banana plants with the pure cultures. The author holds that this disease is not identical with the Panama disease and that it is also different from the two known bacterial diseases of the banana. The name of Bacillus musae n. sp. is therefore proposed for the causative organism.

The disease has been well controlled in Trinidad on small plantations by the immediate destruction of a diseased plant as soon as it is found, and careful sterilization by fire of all tools used in the work.
Sphæropsis tumefaciens n. sp., the cause of the lime and orange knot, Florence Hedges (Phytopathology, 1 (1911), No. 2, pp. 63-65, pl. 1).—The author describes a new species of fungus, *S. tumefaciens*, which produces galls from one-fourth to 3 inches in diameter on the branches of the lime (*Citrus hystrix acida*) and of the orange.

The young tumors are covered by the smooth, green bark, which later usually splits, dies, and falls away, leaving the woody tissues exposed or covered with a softer, more or less crumbly layer about the thickness of ordinary bark. If the mycelium is present in abundance, its dark-colored hyphae impart a black appearance to the tissues of the knot. The fungus rarely fruits in laboratory cultures, but pycnidia containing spores were finally obtained on a 3-months-old corn-meal flask culture of the orange strain. Thus far no perithecia have been observed, but pycnidia and spermogonia occur in great numbers in artificial infections on the host and in cultures of the vigorously fruiting strains from the corn-meal cultures.

A new disease of mulberries, F. Bubak (Ber. Deut. Bot. Gesell., 29 (1911), No. 2, pp. 70-74, fig. 1).—The author describes a new a fungus, *Dothiorcellina tankoffii* n. g. and sp., which is found on dead mulberry branches in the stromatic layers of *Thyrostroma kosaroffii* (*Steganosporium sirakooffii*).

On Melanconis modonia, a parasite of the chestnut in Brittany, V. Ducemet (Bul. Soc. Nat. Agr. France, 71 (1911), No. 1, pp. 99-102).—A description is given of the symptoms of this disease, often known as black canker, as it occurs in Brittany, where it is common in certain localities.

It is claimed that the disease in this region attacks the tops and branches first, and finally works its way downward toward the roots, causing many branches to die and often ringling the trunk, thereby killing the entire tree. The disease apparently begins in the 1-year-old terminal shoots, and is believed to enter by way of the lenticles.

The black canker of the chestnut, G. Briosi and R. Farnetti (Atti. R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5, ser., 20 (1911). I, No. 4, pp. 201-207).—This is a controversial article on the taxonomic position of the fungus *Melanconis perniciosa*, which is claimed by the authors to be the cause of the chestnut canker, and contains critical observations on an article by Griffon and Maublanc (E. S. R., 24, p. 652) in which they claim that *M. perniciosa* and *M. modonia* are identical. The authors, after comparing the characters of the 2 fungi, hold that they are not identical.

The parasitism of *Diaporthe parasitica* on the chestnut, E. Pantanelli (Atti. R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5, ser., 20 (1911), I, No. 5, pp. 366-372).—In addition to a general review of the history of this disease, the author discusses other varieties of *Diaporthe* on the chestnut, and the characters, taxonomic position, germination of spores, and general life cycle of this fungus. It is claimed that inoculation experiments have shown that the fungus is capable of attacking Italian chestnuts, and rigid quarantine regulations are therefore advised against all chestnut plants from the United States.

The chestnut bark disease, F. W. Rane (Boston: State Forester, 1911, pp. 7, pls. 2).—This is a popular discussion of this serious chestnut disease, in which the author describes its growth and symptoms and methods of control and eradication. It is stated that as yet there is no known method of curing the disease or of saving a thoroughly infested woodland, but in regions where the disease has just appeared the prompt destruction of infected trees at the outset is advised.

Hevea disease in Ceylon (Phytophthora faberi), H. N. Ridley (Agr. Bul. Straits and Fed. Malay States, 16 (1911), No. 3, pp. 70, 71).—This fungus attacks both cacao and Para rubber.
In the case of the Para rubber, it attacks the renewing bark on the tapped surfaces, turning it a reddish-purple color, often with a well defined black border, and in advanced cases the bark exudes a purple-brown liquid. Finally the tapped surfaces die back, and black longitudinal streaks appear, which extend through the bark into the wood. The disease is usually discovered by the cessation of latex flow. Intermixed plantations of cacao and Hevea, close planting, and wet weather favor the disease.

**ECONOMIC ZOOLOGY—ENTOMOLOGY.**

A history of British mammals, G. E. H. Barrett-Hamilton (*London, 1910, vol. 1, pls. 1, pp. XVI+8+39+88, pls. 5, figs. 7; 2, pp. 9-16+89-128, pls. 5, figs. 3; 3, pp. 17-24+129-168, pls. 5, figs. 5*).—Volume 1 of this work, of which the first three parts are here noted, is devoted to the Chiroptera, or flying mammals, the genera Nyctalus, Pipistrellus, Vespertilio, and Myotis being here taken up.

South African moles, T. F. Dreyer (*Agr. Jour. Cape Good Hope, 37 (1910), No. 6, pp. 695-698, pl. 1*).—A brief account of the species that occur in South Africa is given.

A history of birds, W. P. Pyrcraft (*London, 1910, pp. XXX+558, pls. 3, figs. 59*).—As stated by the author the aim in writing this book is to present a study of bird life from the viewpoint of the evolutionist and to set forth in broad outline the evidence now generally regarded as bearing on the birth and growth of the various types of birds.

The birds of Australia, G. M. Mathews (*London, 1910, vol. 1, pt. 1, pp. 96, pls. 19; rev. in *Auk, 28 (1911), No. 1, pp. 135, 136*).—This first part of volume 1 contains the Casuariformes (5 species), the Galliformes (9 species), and the Turniciformes (7 species), each illustrated.

Economic ornithology in recent entomological publications, W. L. McAtack (*Auk, 28 (1911), No. 2, pp. 282-287*).—In the course of this review the author presents a revised list of the bird enemies of the gipsy and brown-tail moths, 46 species being recorded as destroying the former and 31 the latter. It is also stated that the Biological Survey records show the killingdeer (*Oxycyclus roeciferus*) and cliff swallow (*Petrochelidon lunifrons*) to be enemies of the hop flea beetle.

Notes on the fruit-eating habits of the sage thrasher in the Yakima Valley, C. H. Kennedy (*Auk, 28 (1911), No. 2, pp. 225-228, figs. 3*).—This is an account of injury by *Oreoscoptes montanus* to raspberries, blackberries, and grapes.

The actual loss in weight of grapes through bird damage to 140 vines of Campbell Early on one ranch was 25 per cent, and the loss in profits was not less than 50 per cent because of the large item of labor in trimming the damaged clusters and the loss in fancy value through the unattractive appearance of the trimmed bunches.

Ten stomachs that were examined all showed that grapes had been eaten. At no time were green and yellowish varieties injured, the thrasher preferring a grape with the two characteristics, a dark color and sourness. It is said that the thrashers were assisted to some extent in their depredations on the early grapes by Bullock's orioles. After the thrashers had left for the South, robins, while flocking preparatory to migrating, injured the very late grapes.

of examining feces to determine the presence or absence of parasites in the alimentary tract that are in use by medical and zoological investigators. He critically compares these methods with the method here proposed, which "consists in breaking up the feces very thoroughly by shaking in water, adding a quantity of small shot if necessary or desirable; sieving through a set of brass sieves and then through a silk bolting-cloth sieve or a sieve made with a jeweler’s fine-meshed brass screen, examining the material left on the sieve for parasites: sedimenting (and washing); centrifuging (and washing)—one tube being filled with calcium chlorid solution of 1,250 specific gravity, centrifuged, and if desired the top cubic centimeter removed with a pipette, shaken up in a tube with 14 cc. of water and centrifuged—and then making a microscopic examination of a drop of sediment from the bottom of the tube centrifuged with water, and one from the top when the calcium chlorid solution alone was used or from the bottom in case water was added to the top cubic centimeter. The material is washed at either or both of the points indicated."

The author considers this method to be the best for routine examination of various kinds of feces, it serving very well for the feces of man and for the carnivora, herbivora, and birds, not only in examining feces for worm parasites but also for coccidia. It has the advantage of speed and certainty over the smear method or sedimentation methods.

A bibliography of 26 titles relating to the subject accompanies the account.

[A note on the viability of nematode eggs and larvae], R. H. Ransom (Abs. in Science, v. ser., 33 (1911), No. 850, p. 592).—Attention is called to the fact that Nematodirus filicollis develops to the ensheathed stage before hatching, a period of about a month being required for the development at a temperature of about 70° F., whereas under similar conditions the stomach worm (Haemonchus contortus) hatches in about 2 days and does not develop to the ensheathed stage until after hatching.

A temperature of 12° was found to kill eggs of the stomach worm (H. contortus) in 7 to 10 days, while eggs of Nematodirus were viable after 8 weeks' exposure to the same temperature. At 32 to 40° eggs of the stomach worm were still alive at the end of 8 weeks but were dead after 13 weeks.

How to control the two worst cotton pests, the boll weevil and the bollworm, P. Hayhurst (Arkansas Sta. Circ. 4, p. 4).—A brief popular account emphasizing the important steps to be taken in combating these pests.

Some insects affecting the tobacco crop, D. B. Mackie (Philippine Agr. Rev. [English Ed.], 3, (1910), No. 12, pp. 706-714, pls. 4).—This is a brief popular account of the insect pests of tobacco in the Philippines. Beneficial insects and remedial measures are included in the discussion.

[Insect enemies of the plum and olive], P. Noel (Bul. Lab. Regional Ent. Agr. [Rouen], 1910, No. 4, pp. 16).—Annotated lists of 254 insects and acarid enemies of the plum and 40 of the olive are presented.

Notes on some Thysanoptera, R. S. Bagnall (Ann. Soc. Ent. Belg., 54 (1911), pp. 461-464).—The author has determined through a comparison of Nearctic specimens with specimens collected in Great Britain, Belgium, Norway, and Denmark, that the North American grass thrips (Anaphothrips striatus) is the same as the old European form A. obscurus. Thus striatus becomes a synonym of obscurus. The type specimen of Anthothrips (Aptinothrips) fasciatus is redescribed and notes are presented on other species.
Papers on deciduous fruit insects and insecticides.—Spraying experiments against the grape leafhopper in the Lake Erie Valley, F. Johnson (U. S. Dept. Agr., Bur. Ent. Bul. 97, pt. 1, pp. 12, pls. 2, figs. 5).—In the vineyards of the Lake Erie Valley serious depredations by this pest are usually confined to somewhat limited areas adjacent to rough lands and woodlots. Periodically, however, some as yet unknown conditions seem to favor its multiplication and it spreads over wide areas, causing injury amounting to many thousands of dollars. During the seasons of 1901 and 1902 many hundreds of acres of vineyards in the vicinity of Westfield, Chautauqua County, N. Y., were seriously injured by the pest, but in 1903 it disappeared to a considerable extent and serious injury was again confined to limited areas until the season of 1910. The author states that the insect is now on the increase and that during the summer of 1910 it spread through large blocks of vineyard, and toward the latter end of the summer its presence in more or less destructive numbers was evident throughout the entire grape belt.

"The adults and nymphs of the grape leafhopper feed upon the underside of the grape leaf and by sucking the juices therefrom cause it to take on a yellowish, mottled appearance which later turns brown, and where the infestation is heavy the leaves dry out and become functionless before the fruit is mature." The adult, in which stage the winter is passed, leaves its winter protection as the days become warmer in early May and commences to feed upon the new growth of almost any plant with which it comes in contact, showing some preference, however, for the foliage of bush fruits, such as wild blackberries, cultivated raspberries, and strawberries. With the unfolding of the leaves, there is a general migration back to the foliage of the grapevine, this being the only plant upon which this particular species of leafhopper is known to reproduce.

In the vineyards of the Lake Erie Valley egg laying by overwintering females does not commence until about June 1, or after the adults have been feeding upon the vines for several weeks. The eggs, which are deposited on the underside of the leaves, are tucked under the skin indiscriminately as to location. "The egg stage covers a period of about 10 days to 2 weeks. The period of egg deposition is obviously a long one, since newly emerged nymphs are present upon the foliage from the middle of June until late in October. Observations indicate, however, that the maximum deposition must occur during the last 3 weeks in June and the first week in July, since the period when there is a maximum number of nymphs upon the leaves is included in a period from the last week in June until about August 1, at which latter date many fully developed nymphs are making their final molt."

The nymphs commence to appear about the middle of June. Five molts take place, the first 4 requiring a period of 5 days for each, while between the fourth and fifth, there is a period of 12 days; thus about a month is required in which to complete the nymphal period. The widespread dissemination of this pest is thought to take place largely during the fall migration and again during the spring migration when the adults leave their winter shelter and return to the vines.

On account of the inability of the nymphs to escape from the underside of the grape leaves, and because of the soft and unprotected condition of their bodies, the nymphal period is the most vulnerable stage of the insect. In observations made during the summer of 1910, the date on which the maximum number of nymphs was found to be present on the foliage before those earliest to hatch had developed their wings and before serious injury had become apparent was July 12. At this time a small number of the nymphs earliest to hatch had entered upon their last molt and the number present upon the leaves in earlier stages of development was very large.
Applications of blackleaf tobacco extract containing 2½ per cent nicotin at dilutions varying from 1 gal. to 75 to 200 of water killed all nymphs hit. Blackleaf "40," which contains 40 per cent nicotin, used at strengths of from 1 to 1,000 to 1 to 1,750 killed all the nymphs hit, and at a strength of 1 to 2,000 killed all but fully developed nymphs. Three acres of a vineyard at North East, Pa., was sprayed in 1 day at a cost of $7.40, $2.40 of which was expended for the blackleaf tobacco extract as applied at a dilution of 1:150, or a total expense of $2.47 per acre. A badly infested vineyard of 11 acres was sprayed July 14 to 16 with blackleaf extract 1:100 at a total cost of $3.75 per acre. On 3 blocks in which the strength of the blackleaf tobacco extract varied from 1:75, 1:100, and 1:150, so far as could be observed the 1:150 dilution was as effective as any. All of the applications mentioned were made before any of the nymphs had completed the final molt and all were highly effective in reducing the number of the nymphs to a point where their injury for the remainder of the season was very slight.

Some synonymy and other notes on Aphidiinae, A. B. Gahán (Proc. Ent. Soc. Wash., 12 (1910), No. 4, pp. 179-180).—This paper includes notes on the host relations of several parasites of this subfamily, the hosts of which have heretofore been unknown. The author also records the occurrence of 4 European species not hitherto credited to our fauna.

The use of potassium permanganate against the woolly aphis, R. Ahrens (Geisenh. Mitt. Obst u. Gartenbau, 25 (1919), No. 11, pp. 182, 183; abs. in Internal. Inst. Agr. [Rome], Bul. Bur. Agr. Intell. and Plant Diseases, 1910, Nov., p. 174).—Favorable results are reported to have been obtained through the use of a 1 per cent solution of potassium permanganate.

Recent results of compounding miscible oils for use in controlling white fly, W. W. Yothers and S. S. Crossman (Fla. Grower, 3 (1911), No. 27, p. 7).—The authors present 4 formulas that they find to give satisfactory results in combating the citrus white fly, viz, (1) caustic potash whale-oil soap 1½ gal., crude oil (not distillate oil) 24° Baumé 3 gal., water to emulsify about 1½ gal.; (2) caustic potash whale-oil soap 2 gal., distillate oil (gas oil) 30° Baumé 4 gal., water to emulsify about 2 gal.; (3) caustic potash whale-oil soap 2 gal., paraffin oil (diamond paraffin oil) 28° Baumé 3 gal., water 1 gal.; (4) caustic potash whale-oil soap 2 gal., paraffin oil (junior red engine oil) 25° Baumé 3 gal., water 1 gal. Each of these contains sufficient ingredients to make up 200 gal. of spray material at a cost of about 63 cts., 84 cts., $1, and $1.05, respectively.

The experimental results obtained from the use of these formulas have been summarized in the following table:

Summary of spraying experiments with miscible oil compounds.

For summer use, formulas (3) and (4) should be diluted to make 300 gal., or spray material containing 1 per cent of oil,
A new scale insect, R. D. Anstead (Planters Chron., 5 (1910), No. 29, p. 372).—The black scale (Saissetia [Lecanium] oleae) is reported from India for the first time, having been found at Kotegiri on Erythrina lithosperma and the upper sides of the leaves of Castilla elastica. It is said to be rapidly spreading on coffee.

Recent work with fungus parasites of scale insects (Agr. News [Barbados], 10 (1911), No. 232, p. 97).—In this brief review it is stated that good results have followed in Barbados and Grenada from the transference of the shield scale fungus (Cephalosporium laccami) to the green and mango shield scales (Coccus viridis and C. mangiferor) on guava and mango plants, and to the mealy shield scale (Pulvinaria pyriformis), which occurs on Java plum (Eugenia jambolana) and rose apple (E. jambos) trees.

On the probable viviparity in some danaiid, i. e., pierid butterflies, N. J. Kusnezov (Trudui Russ. Ent. Obsch. S. Peterb. (Hora Soc. Ent. Ross.), 39 (1910), pp. 634–651, pl. 1).—During the course of anatomical studies of the Danaidae, the author found “fully developed larvae lying in a uterus-like widening of the lower portion of the oviductus communis. . . .

“In all cases these larvae are bent twofold on the seventh body segment and directed with their heads toward the ostium of the ductus seminalis. This situation of the intraterine larve was the same and quite uniform in all my preparations. No chorion was observed which in danaiids is known as a complex and variously ribbed structure. This seeming absence of the chorion may also be considered as an indirect indication of the real viviparity, for this structure could not be destroyed by the method of preparing or absorbed during the short period after the death (post-mortem) of the mother insect.”

Nearly all of the species of danaiids of the Palearctic region were examined, a list of 30 forms being given in which these intraterine larvae were found. Attention is called to the fact that in this list the forms of the genus Colias prevail, especially those characteristic to high northern latitudes or to Alpine altitudes in mountainous countries. Only 2 species of Lepidoptera have previously been recorded as viviparous, namely, Tinea vivipara in Australia and an undetermined tineid species in South America.

An outbreak of destructive caterpillars in Batangas rice fields, D. B. Mackie (Philippine Agr. Rev. [English Ed.], 3 (1910), No. 12, pp. 703–705).—The author reports that in the month of May enormous numbers of caterpillars appeared in Batangas rice fields and destroyed the greater part of the rice crop in the invaded section. Spodoptera maurita is thought to be the species concerned. A large percentage of the rice in certain districts of the Iloilo Province was also destroyed, apparently by the same pest.

Notes on the geometrid Gypsochroa sitellata, H. M. Russell (Proc. Ent. Soc. Wash., 12 (1910), No. 4, pp. 177, 178).—Biological and descriptive notes are given on G. sitellata, which the author reports to have occurred in abundance on pokeweed at Dade City and Orlando, Fla., in the fall of 1907.

Papers on deciduous fruit insects and insecticides.—Life history of the codling moth and its control on pears in California, S. W. Foster (U. S. Dept. Agr., Bur. Ent. Bul. 97, pt. 2, pp. 13–51, pl. 1. figs. 10).—In this paper the author reports life history studies and spraying experiments conducted in the vicinity of Walnut Creek, Cal., during the seasons of 1909 and 1910.

Because of a mean lower temperature in California during the development of the codling moth, there is an increase in the period required for the growth of its respective stages over that observed in the East, especially for the first of the 2 practically full broods of larvae that develop in the pear-growing districts of the interior counties of the State. The second brood, however, is by
far the most destructive of the two, both by reason of its numbers and because of the stage of the fruit when it appears.

In 1909 the first pupa was found on March 11. Four of 300 larvae collected from banded trees during February, 1910, had pupated by March 12. Of the 118 which produced adults in the spring, 95 had pupated by March 31 and all had pupated by April 10. The time spent in the pupal stage is said to vary considerably for different individuals, but all of this brood in 1909 required a month or more, the average time being 39.54 days. It is thought probable that in 1909 the first adult appeared about March 23, as on this date an apparently freshly-shed pupal skin was found and another was discovered in the field on March 27, at which time Bartlett pears were just about in full bloom. In the spring of 1910, moths were seen in the orchard April 9, although none emerged at the laboratory until April 11. The period of emergence of moths is said to last about 2 months.

In 1909 no eggs were laid in the breeding cages until May 7, although many were found in the orchard on May 5. Since practically all moths in the field had emerged by May 6, it is thought improbable that any eggs were deposited in the field after May 15. In 1910 several eggs were found on foliage in the field April 25 at Walnut Creek and on May 2 eggs were numerous throughout the Valley.

One noticeable difference between the life history of the codling moth in California and in the country east of the Rocky Mountains is the increased length of time required for incubation of the first-brood eggs, due to the fact that as a rule there is considerable cool weather, especially at night, during the months of April and May. In the vicinity of Walnut Creek in 1909, the time required for incubation varied from 17 to 22 days, averaging 20.05 days for the individuals under observation. A limited number of observations in 1910 indicated that the incubation period varied from a minimum of 15 to a maximum of over 30 days, the majority requiring about 25 days.

The first larva under observation in 1909 hatched out May 7 from eggs collected in the field. On May 11, 1909, a number of recently hatched larvae were found in the orchard, while on May 11, 1910, young larvae were quite numerous in the field. Of the larvae hatching under observation in 1909, only 29 reached full development in the fruit, from 25 to 42 days being required. "The first larva to leave the fruit in the field was not observed, but on June 5, 3 newly-formed pupae and 29 full-grown larvae were found under bands on 21 pear trees, and 4 pupae and 28 full-grown larvae were found under bands on 10 apple trees. The time from leaving fruit to pupation for this brood, averaging 74 days, would indicate that the first full-grown larva left fruit in late May. Band records and data obtained by bringing in quantities of wormy fruit picked from trees in May showed a maximum number of first-brood larvae leaving fruit June 14 to 26. However, later-maturing larvae of this brood left fruit as late as July 21. In the summer of 1910 many full-grown larvae had left the fruit prior to June 1. At Walnut Creek on June 1, 4 pupae and 248 larvae were taken from the bands on 11 apple trees, and at Suisun on June 3, 10 pupae and 45 larvae were taken from bands on 15 pear trees. The time spent from leaving fruit to pupation varied from 3 to 23 days, with an average of 7.4 days. . . . The first pupae were found in the field June 5, 1909, when a total of 7 were taken with 49 larvae under bands from 21 pear and 10 apple trees. In 1910 pupae were found June 1 and were plentiful in the vicinity of Suisun and Walnut Creek by June 5. . . . Records kept out-of-doors for 165 individuals gave a minimum of 10 days and a maximum of 27 days with an average of 16.3 days for the time spent in the pupal stage. . . . The total time from leaving fruit to emergence
of adults varied from 20 to 47 days, averaging 25.89 days for the individuals under observation. . . . Moths began to emerge June 17 from larvae and pupae collected under bands June 5, reaching a maximum emergence some 2 weeks later, July 4 to 15. . . . From the earliest appearing eggs in spring, about April 15, to the first appearing moths, June 17, gives some 63 days as the approximate length of the life cycle of the first generation. The laboratory records for individuals kept in breeding cages give a life cycle of 71 to 78 days."

In 1909 the second-brood eggs were first found on July 7 at which time 5 larvae that had just hatched, none of which had entered the fruit, were discovered. In rearing cages eggs were deposited in large numbers from July 8 to 10. The time required for incubation was less than half that required for the first-brood eggs. In cages it varied from 7½ to 9½ and averaged 8½ days. The first larvae to hatch out in the laboratory did so on July 12. The first picking of pears in the orchard where the spraying experiment was carried out in 1909 began July 15 and lasted 5 days, during which time young larvae were hatching and entering the fruit in numbers in the unsprayed block so that even the earliest first picking of fruit did not wholly escape the second-brood larvae. In 1910 many second-brood larvae were in the fruit before the first picking.

An average of about 26 days was found to be required for the development of larvae in sound or nearly sound fruit out-of-doors at the laboratory in 1909. "The first larva not pupating but going into winter cocoons in 1909 were taken from bands July 17. Of 78 larvae taken on this date, 38 pupated and adults emerged, 28 died, and 20 went through the winter as larvae. Of 196 larvae and pupae collected under bands on June 28, 1910, 5 did not pupate but wintered as larvae in cocoons." In 1909 the maximum number of larvae and pupae was collected on June 26, while in 1910 the greatest number was found nearly 2 weeks earlier, on June 14. Tables giving the band records and emergence of moths for Walnut Creek and Suisun sections show the maximum emergence of moths to be about 3 weeks earlier than the maximum emergence at San José.

No parasites were reared during the course of the work, but an occasional carabid larva was found under the bands eating the larva and late in the season a number of tenebrionid beetles (Eubolbischrusipes) were found under the bands with partly eaten larva, although in no case were these beetles actually found eating the larva. The effect of sprays on the places of entrance into pears by larvae and commercial results from spraying are reported in detail. All of the plats receiving the first spraying (soon after the falling of the petals) showed a comparatively light infestation at the calyx, and those receiving the two early sprayings had very few pears wormy at the calyx. Those plats on which the first spraying was omitted had a greater percentage of pears wormy at calyx, although they received one thorough spraying just before the first-brood worms began to enter the fruit.

The author finds that as the first-brood larva begin entering the fruit about a month after most of the petals have fallen, though this time may vary somewhat with the season, all spraying for the first brood should be completed within 3 to 4 weeks after the blossoms are off the trees. Two applications for this brood reduced the worms for the season from 0.62 to 18 per cent lower than the plats sprayed once. Two, and preferably 3, treatments are advised, using arsenate of lead at the rate of 4 lbs. to each 100 gal. of water. The first application should be made as soon as most of the petals have fallen; especial pains should be taken to fill as nearly as possible each calyx cup with the poison, and the trees should be drenched. The second treatment should come 3 to 5 weeks after the falling of the petals. The third application should be given 9 or 10 weeks after the falling of the blossoms, or about 2
weeks before the first picking begins. If only 2 treatments are possible, the first and second should be given.

Notes on the life history of the larch case bearer (Coleophora laricella), G. W. Herrick (Ann. Ent. Soc. Amer., 4 (1911), No. 1, pp. 68-70).—This insect is an European species which is gradually becoming widely distributed in the northeastern United States and parts of Canada, causing considerable injury to larch trees wherever present. It devours the small, green leaves in early spring as fast as they push out, on many trees the green tissues being eaten out and the leaves left pale and bleached.

Observations indicate that the larvae molt just before leaving their winter quarters on the branches. They were found active and feeding on April 16, 1910, at Ithaca, N. Y. The first pupa was found in the breeding cages on April 26, the period of pupation lasting from 2 to 3 weeks. In the insectary the first moths emerged on May 11; they began pairing a few days after emergence and on May 31 eggs were found deposited on leaves in the breeding jars. On June 10 the author found eggs in the field in abundance, apparently being placed indiscriminately on either side of the leaves. "Investigation shows that the larva bores through the base of the eggshell and goes directly through the epidermis into the leaf beneath the egg. Here the larvae live, mining in the tissues of the leaf, but growing very slowly. The excrement of the tiny larva is packed behind it in the mine. Here the larvae live until September. . . . The larvae now feed on the leaves of the larches until the latter part of October when they migrate to the branches and go into hibernation."

Two rare leaf enemies of fruit trees, G. Korf (Prakt. Bl. Pflanzenbaun u. Schutz, u. ser., 8 (1910), No. 9, pp. 101-104, figs. 2).—An account of injury caused by the pear-leaf gall midge Perrisia (Cecidomyia) pyri to the pear at Herrenberg and the leaf-vein gall midge Diplosis (Putoniella) marsupialis to the plum at Erlangen, Germany.

A new chironomid miner, V. Willem (Acad. Roy. Belg. Bul. Cl. Sci., 1910, No. 1, pp. 33-36).—The larva of a new species of Cricotopus is said to be found in great numbers on the river Lys, near Ghent in Belgium, where they mine the upper surface of the leaves of the fringed water lily (Limnanthemum nymphaeoides).

Some facts indicating that malaria may be spread through other agencies than the anopheles mosquito. J. Chico (Amer. Jour. Pub. Hyg., 20 (1910), No. 3, pp. 561-565).—The author here presents the evidence which leads him to think that "the anopheles is not the only vehicle for the spread of malarial diseases."

Researches on the development of the ox warble (Hypoderma bovis), C. Vaney (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 5, pp. 283-286).—The author states that in the Lyonnais region, where most of the cattle slaughtered in the summer are of the Charolais breed, the percentage infested by the ox warble varies from 13 to 21.

Notwithstanding that a very careful search was made from September to December in abattoirs at Lyons, the author did not succeed in finding the small larvae either in the dermis or in the subcutaneous tissue of animals examined at slaughter. During the examinations, however, larvae were found in the esophagus and in the beginning of the rumen. Frequently the larvae were very numerous, as many as 22 being found in the same esophagus. The specimens collected were variable in size, their length varying from 4 to 14 mm. The author considers the great difference in the size of the larvae to be sufficient
evidence that they pass the first stage of their development in the submucosa of the anterior region of the digestive tube of their host. This exclusive localization of the young larvae in the esophagus and their absence at the same time from the skin is considered sufficient proof that their entrance is only by way of the digestive tract.

Experiments on transmission of bacteria by flies, with special relation to an epidemic of bacillary dysentery at the Worcester State Hospital, Massachusetts, 1910, S. T. Orton and W. L. Domb (Boston Med. and Surg. Jour., 163 (1910), No. 23, pp. 863–868, fig. 1).—In investigations made during the course of an epidemic of bacillary dysentery, Bacillus prodigiosus planted in the hospital laundry was recovered from flies caught in traps in the scullery and 5 screened ward dining rooms at an interval of from 2 to 6 days after the original plant.

In examinations made for the breeding places of the fly on the hospital grounds a prolific source was found in piles of spent hops and barley malt, brewery waste which had been hauled in for use as a fertilizer. One oz. from the richest portion of such a pile yielded 1,018 maggots. Piles of pig manure mixed with straw bedding, etc., kept outside the piggery building and exposed to the air and rain were also found to be badly infested.

The rôle of insects as agents in the propagation of ergot of the Gramineæ, L. Mercier (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 8, pp. 300–302).—The author finds that the conidia of ergot (Claviceps sp.) on rye grass (Lolium perenne) are conveyed on the hair and in the alimentary canal of a fly (Sciaræ thomæ). It is stated that in the vicinity of Nancy, France, where the observations were made, this fly is very common and is always found on L. perenne.

Concerning the trypanosome in Myoxus nitela and the flea which appears to propagate it, A. Laverean and A. Pettit (Compt. Rend. Soc. Biol. [Paris], 68 (1910), No. 26, pp. 950–952).—The evidence presented indicates that Trypanosoma blanchardi which occurs in M. nitela is transmitted by means of the flea described by Rothschild as Ceratophyllus laversani n. sp.

The rat flea as the intermediate host of a rat tapeworm, W. Nicoll (Brit. Med. Jour., 1911, No. 2620, p. 621).—The cysticercoid stage of Hymenolepis diminuta, one of the most common tapeworms of the rat and an occasional parasite of man, was found by the author in about 4 per cent of the rat fleas (Ceratophyllus fasciatus) dissected.

A single specimen is usually found in each flea although 3 were found in one instance. This same cysticercoid is stated to have been found by Grassi and Rotveli in 4 different insects. "Only 2 instances are yet known of fleas serving as the intermediate hosts of tapeworms. The first of these is the well-known Dipylidium caninum, the larval stage of which is passed in the dog flea and the human flea. The other has been described quite recently by Dampf [E. S. R., 24 p. 758] from the flea Mesopsylla cucta, which is parasitic on the jerboa (Alactaga (Dipus) jaculus)."

A catalogue of the Coleoptera (Coleopterorum Catalogus. Berlin, 1910, pts. 16, pp. 36; 17, pp. 68; 18, pp. 35; 19, pp. 86; 20, pp. 111; 21, pp. 42; 22, pp. 167–351; 23, pp. 174; 24, pp. 137; 1911, pts. 23, pp. 18; 26, pp. 27; 27, pp. 222).—In continuation of this work (E. S. R., 23 p. 464) part 16, by P. Pape, takes up the Brachyceridae; part 17, by Zaitzev, the Dryopidae, Cyathoceridae, Georyssidae, and Heteroceridae; part 18, by E. Csendi, the Platypsyllidae, Orthoperidae, Phaenocephalidae, Discolomidae, and Sphaeridae; part 19, by M. Bernhauer and
K. Schubert, the Staphylinidae; part 20, by A. Schmidt, the Aphodiinae; part 21, by K. Ahlwarth, the Gyrinidae; part 22, by H. Gebien, the Tenebrionidae; part 23, by S. Schenkling, the Cleridae; part 24, by H. Bickhardt, the Histeridae; part 25, by K. W. von Dalla Torre, the Cebrophiidae; part 26, by M. Pic, the Scaptiidae and Pedilidae; and part 27, by A. Raffray, the Psalaphidae.

Further biological notes on the Colorado potato beetle, Leptinotarsa decemlineata, including observations on the number of generations and length of the period of oviposition.—II, Illinois, A. A. Girault and J. Zetek (Annu. Ent. Soc. Amer., 4 (1911), No. 1, pp. 71–83).—A continuation of the studies previously noted (E. S. R., 20, p. 1151).

The elm-leaf beetle, G. W. Herrick (New York Cornell Sta. Circ. 8, pp. 6, figs. 9).—A brief popular account including methods of control.

Budworms in corn (Diabrotica 12-punctata), W. F. Turner (Alabama Col. Sta. Circ. 8, pp. 7, fig. 1).—A popular account of the southern corn root worm, which next to the corn weevil is the worst pest of the corn crop in Alabama.

The application of cold to the destruction of tobacco beetles, G. Poole (Abs. in Chem. Ztg., 34 (1910), No. 126, p. 1127; Internat. Inst. Agr. [Rome], Bul. Bur. Intel. and Plant Diseases, 1910, Nov., p. 177).—Very successful results are said to follow the application of cold in the destruction of tobacco beetles, this practice being commonly employed in Brazil. The tobacco is exposed for about 22 days in absolutely dry inclosures to a temperature of from —3 to —1° C. or preferably to —10°. The immature stages as well as the adults are killed at these temperatures.

The boll weevil advance in Alabama, W. E. Hinds (Alabama Col. Sta. Circ. 5, pp. 6).—It is stated that the boll weevil was on September 3, 1910, found for the first time in Alabama, on the western edge of Mobile County. Its advance was so rapid that by the middle of September the line of infestation included about three-fourths of the county and 10 days later weevils were found in the southern part of Choctaw County. The author considered it probable that by the time of the first frost, they would have reached as far north as the southern part of Pickens County and as far east as Covington County.

The biology of the weevil is briefly summarized and attention called to the importance of the immediate adoption and practice of control measures.

Papers on cereal and forage insects.—The maize billbug (Sphenophorus maidis, E. O. G. Kelly (U. S. Dept. Agr., Bur. Ent. Bul. 95, pt. 2, pp. 11–22, pls. 2, figs. 6).—In this paper the author reports observations made from June to December, 1910.

This beetle, formerly referred to as S. robustus, was found by Chittenden in 1905 to represent a new species which he described as S. maidis. It appears to occur in the entire territory between South Carolina and Texas and northward to Kansas and Missouri, its injury having been reported from South Carolina, Georgia, Alabama, Arkansas, and Kansas; it has also been recorded as occurring in Michigan. Technical descriptions are presented of the larva and pupa, by E. A. Schwarz, with the original description of the adult by Chittenden.

The adults attack young corn plants and probably some of the coarser grasses, as the adults have been found at the base of swamp grass (Tripsacum dactyloides) in considerable numbers, together with larva and pupae. In the latitude of southern Kansas eggs were laid in slits in the sheath of the plant during the month of June, the larvae hatching out in from 7 to 12 days. They at once begin feeding on the tissues of the young corn at the bottom of the egg puncture, directing their burrowing inward and downward into the taproot. When they finish eating the tender parts of the taproot they direct their feeding upward and continue until full grown. This burrowing of the taproot
of the young growing corn plant is disastrous to the root system; the roots, first dying at the tips, soon become of little use to the plant, allowing it to die or to become more or less dwarfed. Eggs are often deposited in plants of even less than one-half inch in diameter. The larvae on hatching burrow into the heart of the plant and cut off the growing bud, thus killing the top; they then direct the burrowing downward only to devour the stub, leaving themselves without food and thus perish. "Plants of more than one-half inch diameter which become infested with larvae make very poor growth, being very slender, rarely reaching a height of more than 2 or 3 ft. before tasseling, and do not produce shoots or ears. Those that do not become infested until they are half grown may produce small ears." Sometimes there are 3 or 4 larvae in the same plant, their burrows often running into each other. In badly infested fields 2 larvae occur quite often in the same plant, although 1 is the usual number and is sufficient to ruin the plant.

"The length of the larval life ranges from 40 to 50 days, as indicated by laboratory observations and checked by collections in the field. They begin maturing and pupating by August 1, pupation reaching the maximum by August 20, and with the exception of a few stragglers all are mature and changed to pupae by September 1. The larvae, on finishing their growth, descend to the lower part of the burrow, to the crown of the taproot, cutting the pith of the cornstalk into fine shreds with which they construct a cell where they inclose themselves for pupation... The pupae occur mostly during the latter part of August and first part of September and are always to be found in their cells in the larval burrows near the crown of the taproot and nearly always below the surface. The pupal period is from 10 to 12 days... The adults begin to issue about the middle of August and continue to do so until the middle of September. Some of them leave the pupal cell, but most of them remain there for hibernation." The adults which hibernate in the pupal cells issue in late spring about the time young corn is sprouting. They kill the small plants outright and injure the larger ones beyond recovery. Females issuing from hibernation commence to oviposit after a few days feeding on young corn. There is only one generation a year.

The pulling up and burning of the stubble is thought to be the most practical means of dealing with the pest and at the same time destroys the lesser cornstalk borer (Diatraea saccharalis). Care must be taken in pulling up infested stalks that they do not break off above the beetle, leaving the pest in the ground. As the infested stalks have a very poor root system, they are easily pulled. Spraying young cornstalks with arsenical fluids at the time the beetles are making their attacks is stated to be very laborious and not very effective.

The alfalfa weevil (Phytonomus murinus), F. M. Webster (U. S. Dept. Agr., Bur. Ent. Cir. 137, pp. 9, figs. 10).—This circular, presenting a brief descriptive account of the alfalfa weevil and the injury it causes, has been prepared chiefly for the purpose of reaching alfalfa growers and obtaining information as to the appearance of the pest in new localities.

It is thought that in dealing with this pest the work of the Bureau of Entomology should be, first, to endeavor to restrict the pest as effectually and as long as possible to its present area of infestation, and, second, to use every means in its power to control it, in the meantime, within this area. Quarantine between the different States is considered wholly useless on account of the agency of the railroads and winds as factors in the dispersion of the beetles. "The most inexpensive and practical means of controlling introductions of the pest by railroads appears to be in the close surveillance of the railroad right of way and the stamping out of incipient outbreaks as soon as discovered."
Diseased bees and combs infected with a minute pathogenic protozoal parasite, apparently the same as Nosema apis found by Zander and Doflein in diseased bees in Bavaria, H. B. Fantham and Annie Porter (Abs. in Nature [London], 86 (1911), No. 2163, pp. 251, 253).—The infected combs used in the study here reported were obtained from Cambridgeshire and Hertfordshire in March. Since infected bee larve were found it is thought quite probable that this parasite is capable of hereditary infection as is the case with N. bombyleis.

Note on a parasite of the black scale of the olive, J. Ruby (Bul. Mens. Off. Renseig. Agr. [Paris], 10 (1911), No. 2, pp. 181, 182).—A brief account of Scutellista cyanca as a parasite of Saissetia (Lecanium) oleae in France.

Transmission of spotted fever by other than Montana and Idaho ticks, Maria B. Mayer (Jour. Infect. Diseases, 8 (1911), No. 3, pp. 322-326).—In the author’s experiments Rocky Mountain spotted fever was transmitted to normal guinea pigs by nymphs of Dermacentor marginatus (from Utah) and Amblyomma americanum that in the larval stage had engorged on infected ones, also by nymphs and adults of D. variabilis (from Massachusetts) that had engorged as larve and nymphs, respectively, on infected guinea pigs.

Transmission of spotted fever by the tick in nature, Maria B. Mayer (Jour. Infect. Diseases, 8 (1911), No. 3, pp. 327-329).—Six hundred and fifty-six ticks were collected during the spring months of 1909; 254 of the species Dermacentor modestus and 492 D. venustus, for the purpose of studying the infectivity of the tick in nature. These ticks were found on cows, bushes, and vegetation in the Lo Lo Valley and Owl Canyon, Mont., and in the vicinity of Pocatello, Idaho. Fourteen groups were arranged, consisting of 25 male and 25 female ticks each. Each group was placed in a new tick-proof sack, with a selected guinea pig of medium size; 9 sacks of Montana ticks (D. venustus) and 5 sacks of Idaho ticks (D. modestus) were arranged in this way.

In 2 of the groups the guinea pig became infected, the ticks of both having been collected from cows in the Lo Lo Valley.

A contribution to the study of Trypanosoma hippicum, A. Laveran (Bul. Soc. Path. Exot., 4 (1911), No. 3, pp. 168-175).—Inoculation experiments made by the author show that T. hippicum can not be identified with T. evansi. He thinks it probable that T. hippicum is the same as the form reported by R. Rangel to be the cause of desregadera in Venezuela, since their morphology and pathogenicity are quite similar. See also a note by Darling (E. S. R., 29, p. 486).

FOODS—HUMAN NUTRITION

Shellfish contamination from sewage-polluted waters and from other sources, G. W. Stiles (U. S. Depl. Agr., Bur. Chem. Bul, 136, pp. 53, figs. 15).—The data reported are based on extended investigations and inspection work carried on in many localities and bacteriological work undertaken to supplement such studies. Existing conditions are in many cases criticized but it is stated that the report “is in no sense intended to discredit the valuable industries concerned, but rather to point the way in which the products of these industries may be accepted with greater confidence by the public.”

Sources of contamination and similar questions are discussed and the results of cooking tests on the bacteriological content of shellfish are reported. The bulletin contains a digest of data on sewage contamination and an extended bibliography.

Quotations from the author’s summary follow:

“There is undisputed evidence to show that shellfish become contaminated when placed in sewage-polluted water, and that *Bacillus coli* and *B. typhosus* will survive for variable lengths of time in the liquor and the body contents of such shellfish after their removal from infected water.

“The presence of sewage organisms in oysters and other shellfish, even in small numbers, may be indicative of great danger; for, where such organisms exist, the specific cause of enteric fever and allied disorders may also be found. . .

“The indiscriminate introduction of sewage into our natural bodies of water is now the greatest enemy to the shellfish industries. In order to correct this evil it will be necessary to prevent further pollution of our waters, or else to remove the shellfish industries from the grounds subject to pollution.

“Oyster beds should be protected from every possible source of contamination, and they should be located in water proven to be pure by repeated examinations. . .

“The practice of floating oysters in water of questionable purity should be absolutely prohibited because of the probability of sewage contamination. When it is desired to remove the gross filth from the exterior of the shell, oysters may be floated and allowed ‘to cleanse themselves’ in suitably constructed devices in waters free from pollution, and containing no less salt than the water in which they will grow to maturity.

“Like other perishable food products, oysters may become unfit for use if stored or kept under insanitary conditions. This spoilage, however, may take place wholly from the length of time out of water.

“Oysters removed from pure beds may become contaminated during the process of shucking or preparation for the market in insanitary shucking establishments. . .

“The liquor in the shell surrounding the oysters contains more bacteria than does an equal volume of meat from the same oyster. This liquor, together with any sand in the gills of the oyster, can be removed and the meat chilled at the same time by the use of pure ice and water. This washing process can be done efficiently within 3 to 10 minutes, depending upon the method employed. Oysters should not be allowed to soak in fresh water, as they increase in volume, change in appearance and flavor, and decompose more rapidly than those not soaked.

“[As shown by cooking tests], steaming contaminated oysters and clams in the shell, or cooking them after shucking for 15 minutes at boiling temperature, practically destroys all organisms of a questionable character, but since in practice shellfish are never cooked for this length of time, cooking can not be depended upon to remove this danger.

“Oysters intended to be eaten on the half shell, above all others, should be produced from beds of unquestionable purity, and they should be consumed preferably while fresh from the beds; although if properly kept at cool temperatures under sanitary surroundings shell oysters may remain wholesome and in good condition for several weeks after dredging.

“The investigations show that vast areas of valuable shellfish grounds in this country are now reasonably free from sewage pollution, but this territory will gradually diminish in size if sewage is not properly cared for in the future. Comparatively speaking, only a small acreage is now subject to serious pollution.”
The food of the oyster and the mechanism of its contamination by polluted water, Fabre-Dormergue (Compt. Rend. Acad. Sci. [Paris], 151 (1910), No. 19, pp. 829-831).—A contribution to the question of shellfish pollution.

Sea mussels and dogfish as food, I. A. Field (U. S. Dept. Com. and Labor, Bur. Fisheries Bul., 28 (1908), pt. 1, pp. 243-257; Doc. 655, 1910, pp. 243-257).—From numerous tests carried on by the author the conclusion is reached that the common sea mussel (Mytilus edulis) is nutritious, palatable, and easily digested. “It contains only half as much waste as the oyster, is more abundant, is more easily cultivated in that it requires less special conditions for growth, and it is adapted for making a greater variety of food preparations. Furthermore, it is in season for the table when the oyster is out of season.” Information is given regarding the cultivation of the sea mussel in Europe.

From tests of culinary qualities, made under a variety of conditions, of the smooth and the horned dogfish, he concludes that the flesh of these fishes is cheap, palatable, nutritious, and easily preserved, and he believes further that it is as digestible as that of other fishes.

“The packing of both mussels and dogfish ought to become a large industry. Conditions are good for creating a market for them. They are a cheap, wholesome food for the masses and constitute a field of opportunity for the fisherman, the packer, and the merchant.”

The paper is followed by a discussion. See also a note by Field (E. S. R., 19, p. 1061).

Studies of fish sausage, L. Bitter (Hyg. Rundschau, 21 (1911), No. 4, pp. 181-189).—Fish sausage is a commercial product, and, according to the author, reasonable in price in comparison with similar goods. Its food properties were studied.

As shown by the results of analysis, the samples contained on an average water 66.64, protein 21.9, fat 9.33, and ash 2.01 per cent.

According to the author, fish sausage is a palatable and useful foodstuff. He states that it should be cooked in boiling water for 25 minutes before it is served.

Studies of poisoning due to canned fish, G. Teyxeira (Staz. Sper. Agr. Ital., 43 (1916), No. 7-9, pp. 646-655).—A contribution to the question of the examination of food products for ptomaines.

The influence of common salt on the bacteria which cause meat poisoning, S. Serekowski and P. Tomczak (Ztschr. Untersuch. Nahr. u. Genussmll., 21 (1911), No. 4, pp. 211-216).—The experiments reported led to the conclusion that from 5 to 10 per cent of salt was not germicidal to the bacteria under consideration. A higher concentration had a retarding effect on ripe colonies, while a 15 to 20 per cent solution hindered the development of Bacillus enteritidis or Proteus varieties. A further conclusion is that salting meat and other preserved foods has prophylactic value when salt is used with sterile materials and when the concentration of the solution is greater than 15 per cent.

Russian process of preserving meat, S. L. H. Slocum (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 83, pp. 138, 139).—A process of preserving meat, devised by M. Vlasевич, is described, which, it is stated, costs about 24 cts. per carcass. It consists in forming on the surface of the meat a thin elastic coating strongly acid in reaction.

In carrying out the process the carcass, with the viscera and head removed, and either with or without the skin, is dipped for a few seconds in a tank filled with a 15 to 20 per cent solution of acetic acid and then hung in the air and dried for 2 or 3 hours. If without the skin, it is then dipped in a solution of gelatin saturated with a 15 per cent solution of common salt. If the carcass is treated with the skin on, only the parts which are exposed are
covered with the gelatin solution. The neck is scarred with a hot iron and covered with salt, and the openings of the large blood vessels are packed with cotton soaked in 80 per cent solution of acetic acid. The treated carcasses are covered with bags to prevent injury from flies.

It is claimed that meat thus treated and stored from 14 to 16 days in summer does not lose its good qualities. The author states that in his experience meat so preserved was palatable after 6 weeks' storage.

The weight of the edible organs and interior fat of animals slaughtered as food—a contribution to the statistics of meat consumption, E. Grams (Das Gericht der als “Fleisch” verwertbaren Organtile und des Eingeweidefettes der schlachtbaren Haustiere; ein Beitrag zur Berechnung des Fleischkonsums, Inaug. Diss., Univ. Bern, 1910, pp. 84).—The author considers that in general the statistics of meat consumption are not accurate, since they are based upon slaughter weights rather than upon the actual amounts of edible material in the carcass. Accordingly, he studied the proportion of edible organs and internal fat in different farm animals used as food.

According to his summary, the amount of such material per 100 kg. gross weight of meat in the case of bulls is 19.24 kg.; steers, 21.5 kg.; cows, 24.88 kg.; and young cattle, 22.22 kg.; or on an average, 21.96 kg. In the case of calves, the amount of organs and fat per 100 kg. of meat was found to be 32.31 kg.; sheep, 26.58 kg.; pigs, 20.89 kg.; and horses, 10.56 kg. A large amount of data is presented regarding the weight of individual organs, and in general the report furnishes data of value in determining the actual meat consumption from slaughterhouse gross weights.

Canned artichokes and artichokes preserved in oil (Bol. Min. Agr. Indus. e Com. [Rome], 9 (1910), Ser. C, No. 11, pp. 35, 36).—The Italian methods of canning artichokes are described.

Honey (Bol. Div. Fomento [Peru], 8 (1910), No. 8, p. 12).—Analyses are reported of 27 samples.

Analysis of Cape gooseberry, W. King (Chem. News, 102 (1910), No. 2666, p. 326).—An analysis is reported of this fruit, which is much used in South Africa for making jams and preserves. The chief food value lies in the sugar which constitutes a little over half of the 17.39 per cent dry matter.

The composition of Cassia fistula fruit pastes, C. Griebel (Ztschr. Untersuch. Nahr. u. Genussmittel, 21 (1911), No. 5, pp. 283–288).—Analytical studies are reported of this material, which is used in a limited way as a food product and also as a drug.

How to use Hawaiian fruits, Jessie C. Turner and Agnes R. Alexander (Honolulu, 1910, pp. 58).—Directions are given for preparing for the table, in a variety of ways, avocado, breadfruit, mango, and many other fruits peculiar to or commonly grown in Hawaii.

Brewers' yeast as an article of diet, F. Hayduck (Umschau, 15 (1911), No. 10, pp. 195–197).—Information is summarized regarding the preparation and use of yeast as food and also as a feeding stuff.

Cream of tartar, A. McGill (Lab. Inland Rev. Dept. Canada Bul, 222, pp. 41).—Out of a total number of 339 samples collected in the Dominion of Canada, 88 were found up to the British Pharmacopoeia standard, 200 were up to the commercial standard, and the remainder were below this standard or adulterated.

The occurrence of poisonous metals in foodstuffs, C. Formenti (Ztschr. Untersuch. Nahr. u. Genussmittel, 21 (1911), No. 5, pp. 265–274).—The author summarizes the results of the investigations which he has carried on regarding the possible accidental contamination of food materials by the use of tin containers, metal rollers, and in similar ways.
Changes in the physical and morphological character of foodstuffs, meat, fish, and milk by cold, Bützler (Deut. Schlacht u. Viehhof Ztg., 10 (1910), Nos. 45, pp. 623, 642; 46, pp. 639-641).—Experimental and other data are summarized in this discussion of the effects of cold storage on food products, which was presented at the Second International Cold Storage Congress in Vienna.

Municipal chemistry, edited by C. Baskerville (New York and London, 1911, pp. IX+526, figs. 251).—This volume contains a series of lectures on the application of the principles of chemistry to the city, delivered at the College of the City of New York during 1910.

Among the subjects included may be mentioned the following: The Purpose, Method, and Extent of Food Adulteration, and The Remedy of Food Adulteration and Relation of Chemistry Thereto, by H. W. Wiley; Food Inspection, by W. A. Hamor; Ventilation, by H. R. Moody; The Chemistry of Personal Hygiene, by T. A. Storey; Textile Materials and Their Service to Man, by L. A. Olney; and Street Sanitation with Some Special References to New York City, by W. H. Edwards.

[Food inspection and related topics], A. H. Jones (Ann. Rpt. State Food Comr. Ill., 10 (1909), pp. 1-266, 269-302, 306-444, 452-458, pl. 1, figs. 2).—In addition to the usual reports, a compilation of legislative enactments, tentative food standards, financial statements, and similar data, the report contains details of the analytical work carried on. Out of a total of 7,551 samples of baking powder, catsups, oleomargarine, coloring matters, extracts, milk, and other food products examined, 4,786 were declared to be legal and 2,765 illegal.

Fourth annual report of the chemical department of the laboratory of hygiene, H. E. Barnard (Ann. Rpt. Bd. Health Ind., 28 (1909), pp. 259-330, charts 2).—The food and drug inspection work carried on during the year is summarized. A large number of samples of milk and other dairy products, sausage, lard, maple products, beverages, and miscellaneous food products were examined.

[Alum in pickles, bleaching flour, board of health regulations regarding minimum standards for food and drugs, and other pure food topics] (Ann. Rpt. Bd. Health Ind., 28 (1909), pp. 88-95, 189-298).—Circular letters, standards proposed by the state board of health, the rules of the Indiana State Board of Health governing chemical analyses and bacteriological and pathological examinations, and other data are presented.

Food commissioner's report, H. P. Jones (Bien. Rpt. La. Bd. Health, 1908-9, pt. 1, pp. 229-269).—The work carried on under the state pure food and drug law is summarized. Analyses and bacteriological studies of milk are reported, and a number of food topics are discussed.

Food inspection department (Bien. Rpt. La. Bd. Health, 1908-9, pt. 2, pp. 45-65).—Information is summarized regarding the inspection of meat, milk, and bakeries in New Orleans, the ordinances are quoted regarding bakery inspection and the handling and sale of foodstuffs, and details are given regarding the examination of dairy products, meat products, and other food materials, water, formaldehyde, and miscellaneous products. The total number of samples examined was 4,751, the bulk of them being milk samples.

Annual report of the food and drug commissioner, Missouri, 1910, W. P. Cutler (Ann. Rpt. Food and Drug Comr. Mo., 1910, pp. 87).—During the year 608 samples of milk and other dairy products, meat products, flour, miscellaneous food products, cattle feed, and drugs were examined, of which 272 were
declared to be adulterated or misbranded. It is stated that the work of the laboratory has been confined mainly to the examination of milk, cream, ice cream, butter, vinegar, and flavoring extracts.

In addition to details of the analytical work, the report contains some general discussions of pure-food topics.

Report of food and drug inspection, C. D. Howard (N. H. Sanit. Bul., 3 (1911), No. 13, pp. 240–262).—Data are reported regarding the examination of a large number of samples of milk and other dairy products, flavoring extracts, oysters, maple products, olive oil, canned goods, and other food materials, and of a number of samples of drugs.

Eleventh annual report on food adulteration under the pure food law, W. M. Allen and W. A. Smith (Bul. N. C. Dept. Agr., 31 (1910), No. 12, pp. 107).—Out of a total of 1,203 samples of baking powder, butter, catsups, beverages, ice cream and ice-cream substitutes, lard, maple syrup, vinegar, and other materials examined, 16.29 per cent were declared illegal.

The report includes data regarding prosecutions under the law and other matters pertaining to the work.

Ninth annual report of the food and dairy commissioner of the State of South Dakota, 1909, A. H. Wheaton (Ann. Rpt. Food and Dairy Comr. S. Dak., 9 (1909), pp. 95).—Details are given of a large number of samples examined under the state pure-food law, together with lists of butter makers, reports of creameries, financial statements, reports of officials, and similar data.

Tenth annual report of the food and dairy commissioner of the State of South Dakota, 1910, A. N. Cook (Ann. Rpt. Food and Dairy Comr. S. Dak., 10 (1910), pp. 114).—Out of a total of 627 samples of canned goods, dried fruits, flavoring extracts, vinegar, spices, linseed oil, paints, stock feeds, and miscellaneous products examined under the state pure food and drug law, 127 were not passed.

In addition to details regarding the examination of foods and the usual financial statements and reports, recommendations are included for laws regarding publicity, clean food, and net weight.

[Miscellaneous food topics], J. Foust (Penn. Dept. Agr., Mo. Bul. Dairy and Food Div., 8 (1911), No. 12, pp. 107).—Data are given regarding the analysis of dairy products, beverages, vinegar, and miscellaneous food materials under the state pure food law, miscellaneous food topics are discussed, a list is given of the licenses issued for the manufacture and sale of oleomargarine and renovated butter, and a summary is presented of other work carried on.

Laws of Wyoming providing for pure food, drugs, drink, and illuminating oils (State Dairy, Food and Oil Comr., 1911, pp. 15).—Legislative enactments on these subjects are summarized.

How to plan meals, Emma S. Jacobs (Jour. Home Econ., 3 (1911), No. 2, pp. 162–168).—In this discussion of family dietetics the author gives menus which she considers correctly balanced and which show the amount of each food, its cost, and its protein and energy content. To facilitate computing such data for any given dietary, she has prepared a table showing the weight, cost, and protein and energy content of individual portions of a number of common foods, the cost being based on retail figures in the Washington, D. C., market in January. 1911.
Food economy (Bull. Kans. Bd. Health, 7 (1911), No. 2, pp. 36-45, chart 1).—In connection with this general discussion of food and the principles of nutrition data are summarized in chart form regarding the amounts of nutrients and energy which can be purchased for 10 cents in a number of food materials, the values being based on prices current in Topeka, Kans., June 20, 1910.

Food and efficiency of the rural population, J. KAUP (Ernährung und Lebenschraft der Ländlichen Bevölkerung. Berlin, 1910, pp. VIII+576).—Statistical and sociological data have been collected for the different German provinces and similar information for a number of other countries is briefly summarized.

In the concluding section the author discusses such subjects as changes which have taken place in the dietary habits of the rural population; the utilization of milk and milk products in town and country districts; the insufficiency of the national milk supply and means of increasing it, notably by an increased importation of butter; and the dissemination of information on hygiene in country districts. In general, he indicates that the admitted physical deterioration of the rural population which he is considering is in large measure due to the smaller amounts of milk and milk products now consumed and the substitution for them of less nutritious or even harmful materials, such conditions being due to the inadequacy of the general milk supply.

The relationship of food to physical development, D. McCAY (Philippine Jour. Sci., B. Med. Sci., 5 (1910), No. 2, pp. 163-170).—In this discussion the author summarizes investigations reported in full elsewhere (F. S. R., 24, p. 508) in support of his theory that there is a close relationship between the nutritive value of the diet, and particularly its protein content, and physical development. This he believes is clearly brought out in a comparison of the degree of nitrogenous interchanges of a number of native races, arranged according to the amount of nitrogen per kilogram of body weight. At the head of the list are the Bengalis, with 0.42 gm., and the Tibetan and Bhutan Bhutias, with 0.35 gm., respectively, of nitrogen per kilogram of body weight and with a large amount of animal food in the diet, and at the bottom of the list are the Oorlyas, with 0.116 gm. of nitrogen per kilogram of body weight.

The perils of low protein diets, A. Broadbent (Veg. Messenger and Health Rev., 8, ser., 8 (1911), Nos. 3, p. 82; 4, pp. 123-125, chart 1).—The author is of the opinion that a low protein diet does not favor longevity and in proof of this cites facts which he has observed through a long period with aged vegetarians. A discussion follows the second paper.

A contribution to the theory of protein metabolism, K. Schrage (Beitrag zur Lehre von Eiweissstoffwechsel. Inaug. Diss., Univ. Bern, 1909, pp. 15).—Although the experiments reported, according to the author, did not lead to general conclusions, they indicate that the nitrogen retained on a high protein diet is not of necessity excreted again.

Concerning the extractives of muscular tissue.—XI, A comparative study of the nitrogenous extracts of veal and beef, W. Skworzow (Ztschr. Physiol. Chem., 68 (1910), No. 1, pp. 26-39).—The total amount of nitrogenous material in the aqueous extract of beef and veal was much the same, ranging from 0.38 to 0.42 per cent, but there were differences in the proportions of the different extractives present.

Nitrogen partition in feces, H. Labbé (Compt. Rend. Acad. Sci. [Paris], 151 (1910), No. 19, pp. 832-824).—By means of different extractives the author studied nitrogen partition in feces. His results, in general, showed that of the total nitrogen 45.25 per cent was soluble and 54.75 per cent insoluble. The character of the portions extracted by different solvents is briefly considered.
The synthesis of fatty acids in the body, O. Porges (Ergeb. Physiol., 10 (1910), pp. 1-38).—A summary and digest of data on the subject of fat formation in the body. Among other questions the author considers the oxidation of saturated and unsaturated fatty acids, the relationship between the constitution of a fatty acid and its utilization by the body, and the combustion of fatty acids in relation to the utilization of nutrients.

The synthesis of fat in body cells and the question of the relationship of its composition to fat in food. E. Abderhalden and C. Brahm (Ztschr. Physiol. Chem., 65 (1910), No. 4, pp. 320-335).—The authors distinguish between deposited fat and true cell fat. When the fat deposited after feeding large amounts of mutton tallow or rape-seed oil was extracted, it gave the reaction of the fats fed. The cell fat was separated from the deposited fat by digestion with gastric juice or with dilute hydrochloric acid and its composition was found not to depend upon the kind of food eaten.

The digestibility of connective tissue, R. Baumstark and O. Cohnheim (Ztschr. Physiol. Chem., 65 (1910), No. 5-6, pp. 477-482).—As a result of experiments with animals the conclusion was reached that connective tissue is completely digested by pepsin or in the digestive tract. Raw connective tissue is digested by pepsin and hydrochloric acid only, though this digestion may take place beyond the pylorus.

The rôle of electrolytes in the saccharification of starch by the salivary and pancreatic amylases, M. Lissonne (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 4, pp. 132-134).—The experiments briefly summarized emphasize the importance of electrolytes in digestive processes.

On the presence of allantoin in certain foods, H. Ackroyd (Bio-Chem. Jour., 5 (1911), No. 8-9, pp. 400-406).—Bread, milk, vegetables, bananas, and rhubarb were included in the author’s investigation.

His general conclusions are that "the whole quantity of allantoin excreted by man on a milk and vegetable diet may be derived directly from the food. Milk, white bread, French beans, green peas, all contain small quantities of allantoin, while none could be isolated from eggs, bananas, or rhubarb."

The utilization of the mineral salts of milk by nursing infants, F. Barre (Rev. Hyg. et Méd. Infant., 10 (1911), No. 1, pp. 37-45).—The results of experiments are reported.

Experiments on the metabolism of phosphorus, J. P. Gregersen (Ztschr. Physiol. Chem., 71 (1911), No. 1, pp. 49-99).—From his experimental data the author concludes that the body can remain in phosphorus equilibrium through a long period, or indeed make gains on a nitrogenous diet with phosphorus supplied entirely in inorganic combination.

It would appear, therefore, that the body can build up organic phosphorus compounds from phosphates and phosphorus-free organic substances. The loss of phosphorus on a nitrogen-free diet is not affected one way or the other by feeding phosphates. If the body is maintained in nitrogen equilibrium on a diet containing albumin but free from phosphorus, the phosphorus excretion is markedly diminished. In some cases so much so that it represents only one-fiftieth to one-sixtieth of the amount of nitrogen excreted. On a phosphorus-free diet containing albumin and calcium and magnesium salts, the urine contained only a minimum amount of phosphorus, a quantity less than one-tenth of the amount excreted in the feces during the same period. On the other hand, on a similar diet containing neither calcium nor magnesium salts, the urine usually contained more phosphorus than the feces, and this was also the case on a phosphorus-free and albumin-free diet which contained calcium and magnesium salts.

The experiments were made with rats.
Digestive processes, E. Bardier (Les Fonctions Digestives. Paris, 1911, pp. VII+538+XII, figs. 29).—In this handbook the composition of tissues, the general phenomena of digestion, mastication and muscular movements of the digestive tract, absorption, and other related topics are considered.

This is one of the volumes included in the series Encyclopedie Scientifique.

Fasting studies.—II. On the catalase content of tissues and organs after prolonged fasting, P. B. Hawk (Jour. Amer. Chem. Soc., 33 (1911), No. 3, pp. 425-431).—From chemical studies of the tissues of fasting dogs in comparison with normal animals, the general conclusion is drawn that fasting tends to lower the catalytic power of the tissues. In the case of a dog which had fasted for 2 periods, with an interval between, the tissues possessed catalytic powers which were much more comparable with normal tissues than was the case with a dog which had fasted for but a single period.

Discussing his results in comparison with other data, the author believes that the information reported regarding “higher catalase values for the tissues of adult ‘repeated fasters’ as compared with adult ‘initial fasters’ may be taken as indicating the more efficient functional activity of the repeated faster.”

The metabolism and energy transformations of healthy man during rest, F. G. Benedict and T. M. Carpenter (Carnegie Inst. Washington Pub. 126, pp. VIII+255).—In this report the authors have summarized data collected during the 10 years or so in which experiments were carried on with the respiration calorimeter at Wesleyan University, Middletown, Conn., including work carried on in cooperation with the United States Department of Agriculture. The bulk of the material included has not been previously reported.

Among the subjects discussed in detail are changes in body weight, insensible perspiration, body temperature with its variations and fluctuations, and pulse rate. Important data obtained with the respiration calorimeter are reported regarding the vaporization of water from the body of the subject, the elimination of carbon dioxide, the consumption of oxygen, and heat elimination and heat production. Special reference is made to comparisons between the metabolism during sleep and during waking hours. The authors also consider the relationships between the various factors of metabolism, including the relation of carbon dioxide eliminated to water vaporized, the respiratory quotient, the caloric equivalents of carbon dioxide and oxygen, and the relations existing between carbon dioxide elimination, oxygen consumption, and heat production, and the relation of muscular work to these 3 factors. Special attention is likewise given to variations in metabolism due to variations in physical characteristics, age, muscular activity, sex, etc., of the subjects, including the metabolism of athletes, nonathletes, and women. A number of experiments are included which deal with the metabolism and energy transformations incidental to simple every-day body movements, such as dressing and undressing, standing, sitting, etc. In conclusion, tentative tables based on these data are given for computing the metabolism of normal individuals with varying degrees of muscular activity.

The following table gives the carbon dioxide eliminated, the oxygen absorbed, and the heat produced per hour during various activities, the data as to standing and very severe muscular exercise being calculated using as a standard the results obtained with 55 men awake and sitting up.
Carbon dioxide elimination, oxygen absorption, and heat production per hour during various activities.

"The results presented in this report are to be considered simply as indicating the normal metabolism of healthy young men at rest and under several conditions of muscular activity. The variations from the normal exhibited by the individual can be seen by an examination of the tables. The attempt is made to point out the cause of the variations in so far as possible, but with so complex a process as the energy transformation and katabolism in the body, it is clearly futile to attempt to predict with great accuracy either the katabolism or the energy transformations of a given individual. Approximate values that may prove of practical use can be obtained by means of some of the factors outlined in this report. With more accurate and improved calorimeters, there should be in the course of a few years the addition of many factors, at present entirely unknown."

Old age deferred, A. Lorand (Philadelphia, 1910, pp. XI+458).—Factors which affect longevity are discussed. Chapters are included on such topics as the hygiene of the intestine, rational clothing, the production and destruction or elimination of toxic bodies, the relation of different foods and dietary habits to the question of long life, and related matters.

Practical dietetics with reference to diet in disease, Alida F. Pattee (Mount Vernon, N. Y., 1910, 6. ed., pp. XXX+527, figs. 9).—A considerable amount of new matter has been included in this revised edition, particularly data regarding the fuel value of the foods and diets under consideration.

The author states that Mary D. Swartz Rose has assisted in the revision.

Pattee's handbag diet book, Alida F. Pattee (Mount Vernon, N. Y., 1911, pp. VII+186, figs. 2).—The material, reprinted from the author's Practical Dietetics with Reference to Diet in Disease (see above), consists chiefly of recipes and data regarding the preparation of invalid dishes and diets. It is designed especially for the use of nurses and it has been the author's purpose to present the material in a small volume which could be carried in a nurse's handbag.

The use of rice bran in the prevention and cure of beriberi, L. Béraudat and Dentier (Ann. Inst. Pasteur, 25 (1911), No. 2, pp. 167-189, figs. 5).—This discussion includes statistical, experimental, and analytical data. The general conclusion drawn is that 40 gm. of rice bran per day exercised preventive and curative action.

An extended bibliography is appended.

ANIMAL PRODUCTION.

The genotype conception of heredity, W. Johannsen (Amer. Nat., 45 (1911), No. 531, pp. 129-159, figs. 6).—The transmission of personal qualities is regarded as a naive and now antiquated conception of heredity; likewise, the biometrical definition of heredity as the correlation between parent and off-
spring. That personal qualities of an offspring are the reiteration of the gametes joined to form a zygote is the genotype conception, and personal adaptation is, in the view of the author, a matter of little importance. Heredity is defined as the presence of identical genes in ancestors or descendants. The genotype conception is advocated because of its value for further critical research rather than as a full explanation of heredity. See articles noted below.

Inheritance of acquired adaptations, P. Kammerer (Flugschr. Deut. Gesell. Züchtungsk., 1910, No. 12, pp. 52; Arch. Entwickl. Mech. Organ., 17 (1906), No. 2-3, pp. 165-264, pl. 1; 25 (1907), No. 1-2, pp. 7-59, pl. 1; 28 (1909), No. 4, pp. 477-545, pls. 2; 29 (1910), No. 3-4, pp. 535-408; 30 (1910), No. 1, pp. 379-408; Sci. Amer. Suppl., 79 (1910), No. 1804, p. 76, figs. 4; 71 (1911), No. 1829, p. 36; Ztschr. Induktive Abstam. u. Vererbungslchr., 4 (1911), No. 3-4, pp. 279-288, pls. 3; rec. in Naturw. Rundschr., 26 (1911), Nos. 1, pp. 6-8; 2, pp. 20, 21).—Results of experiments with toads, lizards, and salamanders extending over a series of years lead the author to infer that the changes in color and other adaptations brought about by environment are inherited.

The determination of dominance and the modification of behavior in alternative (Mendelian) inheritance, by conditions surrounding or incident upon the germ cells at fertilization, W. L. Tower (Biol. Bul. Mar. Biol. Lab. Woods Hole, 18 (1910), No. 6, pp. 285-353, pls. 8, figs. 4).—This is a paper presented at the meeting of the American Naturalists in Boston, in December, 1909. Three species of chrysomelid beetles of the genus Leptinotarsa, which hybridize freely, namely L. signaticollis, L. undecimlinata, and L. diversa n. sp., were used in the investigation.

Some effects of temperature upon growing mice, and the persistence of such effects in a subsequent generation, F. B. Sumner (Amer. Nat., 45 (1911), No. 530, pp. 90-98).—A discussion of the necessary conditions for the fair test of the question as to the inheritance of acquired characters. Brief reference is made to the significance of the results obtained by the author (E. S. R., 22, p. 378), Tower, Kammerer (noted above), and other investigators.

Further investigations on changes in species, especially the nature of quantitative specific differences in daphnids, R. Woltereck (Verhandl. Deut. Zool. Gesell., 1909, pp. 110-113, figs. 18; abs. in Zool. Zeit., 17 (1911), No. 23-25, pp. 756-760).—When daphnids were overfed for several generations a widening of the head and other changes took place. After 2 years the original head form was not displayed by the young, even when returned to normal nutritive conditions, and the effect of the environment appeared to be permanently inherited.

The author maintains that a new genotype was produced by the continued action of the culture medium.

Organic response, D. T. MacDougall (Amer. Nat., 45 (1911), No. 529, pp. 1-40, figs. 5; Science, u. scr., 33 (1911), No. 838, pp. 94-101; Sci. Amer. Suppl., 71 (1911), No. 1833, pp. 122, 123).—A number of investigations, including the work of Tower, Sumner, and Woltereck, noted above, are reviewed, and the author's own investigation with plants is given in detail to show that external agencies acting upon a great variety of organisms have been seen to result in the appearance of new types of genotypes, which have been found to transmit their characters perfectly through so many generations as to indicate practical permanency. These changes may be regressions, awakened latencies, or organizations de novo, and the alterations induced by external agencies may be cumulative or mutative as to appearance or organization. They may be permanent upon first appearance, or, on the other hand, may need generations of repetition before becoming fixed.
The author presents a very strong case in support of the theory of inheritance of acquired characters, and concerning his own method of studying evolution says: "The actual transplantation of organisms from one locality to another, as a method of experimentation, promises the results of highest value and widest significance, especially when taken in connection with analytical laboratory cultures. This method of approach is one which may yield evidence of the greatest value upon the influence of isolation and other geographical factors, but is also one which allows the repetitive or mnemonic effects to be evaluated. When supplemented by laboratory analyses and cultures to determine the nature of alterations induced, such methods promise results of the greatest value."

Recent work on the inheritance of acquired characters, W. B. Alexander (Zoologist, 4, ser. 14 (1910), No. 168, pp. 441-450).—A résumé of investigations by Strandfuss, Tower, Kammerer, and others on this topic.

Recent literature on Lamarck and Lamarckism, W. May (Zool. Zentbl., 18 (1911), No. 1-2, pp. 1-20).—A review of recent literature bearing on the inheritance of acquired characters, with a bibliography of 40 titles.

A sketch of Mendel's life and work, D. J. Scourfield (Mendel Jour., 1911, No. 2, pp. 15-33, fig. 1).—A brief résumé of Mendel's work in heredity.

The nucleus and heredity, V. H. Blackman (New Phytol., 10 (1911), No. 3, pp. 90-99).—A statement of the reasons for assigning to the nucleus the major part in the transmission of hereditary traits.

The application of the conception of pure lines to sex-limited inheritance and to sexual dimorphism, T. H. Morgan (Amer. Nat., 45 (1911), No. 530, pp. 65-78).—This article discusses the treatment of sex as a Mendelian character, the relation between sex and the inheritance of secondary sexual characters and the bearing of sex-limited inheritance on the problem of the transmission of characters in general.

On the effect of a differential fertility on degeneracy, K. Pearson (Biometrika, 7 (1910), No. 3, pp. 258-275, dgsms. 2).—A mathematical demonstration that when there is a correlation between fertility and any character giving rise to genetic or reproductive selection, it may largely neutralize or wholly defeat the results of natural selection. In wild life it is difficult to find any character perceptibly correlated with fertility, but with domesticated animals and in the case of man a differential fertility has been artificially established and the influence of natural selection lessened.

Fertility of hybrids between Bison americanus and B. europæus, E. Iwanoff (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 14, pp. 584-586).—Hybrids of both sexes proved to be fertile.

On the determination of the chief correlations between collaterals in the case of a simple Mendelian population mating at random. E. C. Snow (Proc. Roy. Soc. [London], Ser. B, 83 (1910), No. B 561, pp. 37-55).—A mathematical demonstration of the correlation of siblings (brothers or sisters), eldersibs (uncles or aunts) with sibmags (nieces or nephews), and of cousins in a random population.

The somatic correlation between siblings was found to be greater than that between parent and offspring. Grandparental correlation was the same as avuncular, while that of cousins is greater than that of grandparental. The ancestral and collateral correlations in man and certain animals, founded on biometric research are collected in the table following.
Mean ancestral and collateral correlations in man and animals.

Computing correlation in cases where symmetrical tables are commonly used, H. S. Jenning (Amer. Nat., 55 (1911), No. 530, pp. 123-128).—A method of computing the coefficient of correlation from ordinary tables by which much labor can be saved in studying assortative mating. See also a note by Harris (E. S. R., 24, p. 375).

An abac for determining the probable errors of correlation coefficients, D. Heron (Biometrika, 7 (1910), No. 3, pp. 411, 412, chart 1).—By means of this abac the probable errors of correlation coefficients can be read off at once correctly to at least two decimal points.

Report of the first International Congress of Breeding and Feeding (J. Cong. Internat. Élevage et Aliment., 1910, Compl. Rend., pp. 168).—This contains a list of the members, the proceedings of the meeting, and reports of some of the papers read.

Reports of the first International Congress of Breeding and Feeding (J. Cong. Internat. Élevage et Aliment., 1910, Raps., pp. 524-63).—This is a report of the papers read at the meeting held in Brussels, 1910.

The new respiration apparatus at the Berlin Agricultural College, N. Zuntz (Umschau, 15 (1911), No. 5, pp. 92-97, figs. 4).—A popular illustrated description of the respiration calorimeter for experiments with farm animals, which the author has recently installed. See also a previous note (E. S. R., 22, p. 375).

Chemical analyses of licensed commercial feeding stuffs, 1910, F. W. Woll (Wisconsin Sta. Circ. Inform., 22, pp. 109).—This is a report of the feeding stuff inspection of 1910. Analyses are reported of linseed oil meal and cake, cottonseed meal, distillers’ grains, gluten and hominy feeds, wheat bran and middlings, red dog flour, rye feed, barley shorts, buckwheat feed, corn-and-cob meal, germ meal, dried brewers’ grains, malt sprouts, alfalfa meal, rye bran and middlings, buckwheat hulls, blood meal, beef scrap, tankage, wheat screenings, oat hulls, clover hay, clover straw, marsh vetch (Lathyrus palustris), timothy hay, green silage, ground oats, flax screenings, ground corn cobs, ground cornstalks, green sweet corn, cocoa bean shells, green clover, and many mixed feeds.

Licensed commercial feeding stuffs, 1911, F. W. Woll (Wisconsin Sta. Circ. Inform., 24, pp. 1-11).—A list of licensed manufacturers of concentrated commercial feeding stuffs for the calendar year ending December 31, 1911.

The lecithin content of meadow grass, J. Beckee (Fühling’s Landw. Ztg., 59 (1910), No. 12, pp. 420-424; abs. in Zentbl. Agr. Chem., 90 (1911), No. 2, p. 144).—An application of Thomas slag was found to increase the lecithin content of fresh meadow grass.

A contribution to the effect of plasmase, L. Greve (Berlin. Tierärztl. Wehnschr., 26 (1910), No. 23, pp. 464–466).—This preparation was found to contain cinnamic acid, phosphoric acid, and arsenic in organic compounds. In experiments with swine, horses, and one cow the growth was stimulated in the case of only one animal.
Experiment station record.

Fattening cattle on blue grass pasture, F. B. Mumford (Missouri Sta. Bul. 90, pp. 289-388, figs. 5).—A report of a 5-year series of tests in steer feeding in cooperation with this Department.

The steers used were high grade but not pure bred. The number in each lot fed varied from 6 to 10, and in all over 300 head were fed. The length of the feeding period was usually about 210 days, but in 1907 it was only 147 days. The following scale of prices was used for computing the financial statement: Shelled corn 40 cts. per bushel; linseed meal $28, cottonseed meal $24, and gluten feed $22 per ton; and pasture, yearlings 60 cts. and older cattle 75 cts. per head per month.

The following table shows the average daily gains and cost per pound gained with the different rations:

*Experiments in fattening cattle on grain and blue-grass pasture.*

</tbody>
</table>

The results of the five years' work show that in general the gains were more uniform and a better finish was obtained when corn was supplemented with other grain. The fatter the animal the more efficient were the supplemented rations, and hence it was profitable to feed a limited amount of nitrogenous supplement during the later stages of the feeding period. Though young cattle made faster gains with nitrogenous supplements, the increase was not sufficient in most cases to make it profitable.

The influence of bedding on gains in steers. B. Tacke (Oldenburg. Landw. Hr., 58 (1910), No. 40, pp. 337-389; abs. in Zentbl. Agr. Chem., 40 (1911), No. 2, pp. 99-101).—In a number of tests with steers those which were bedded with...
straw made faster gains than those without. Peat as a bedding gave better results than straw bedding.

Raising calves on skim milk, C. H. Eckles and G. C. White (Missouri Sta. Circ. 47, pp. 99-106, figs. 3).—A circular containing practical information on raising calves by hand, the use of milk substitutes in calf feeding, and the general management of calves.

Cattle breeding in the district about Tabora, WÖLFEL (Pflanzer. 7 (1911), No. 2, pp. 77-85).—An account of the extent of the cattle industry in the central part of German East Africa, methods of management, and suggestions for improvement.

The woolen and worsted industries, J. H. CLAPHAM (London, 1907, pp. XII+307, pls. 21).—A general treatise on the production, commerce, and manufacture of wool and woolen goods.

On the alleged influence of the Steppes climate and vegetation of Bokhara on the characteristics of the caracal fleece, L. ADAMETZ (Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 3, pp. 235-303).—A report of a detailed study of meteorological factors and food plants in the regions where the caracal sheep are raised. The author does not find that the peculiar character of the fleece is due to the soil, water, feed, or climate, but that it is a racial peculiarity of the sheep which is inherited, and consequently can be produced in other countries under favorable conditions.

Concerning the zebu and animal breeding in Germany, E. AUGUSTIN (Deut. Landw. Tierzucht, 15 (1911), No. 12, pp. 142-144).—The advantages of the zebu as a domesticated animal are discussed.

Observations with camels, W. MEISSNER (Ztschr. Veterinärk., 22 (1910), Nos. 6, pp. 279-287; 7, pp. 313-331).—This is a general account of the anatomy, conformation, and characteristics of camels, and their value as transport animals. Practical hints are given for their feeding and management in health and sickness.

Farmers’ handbook on swine, A. K. SHORT (Arkansas Sta. Circ. 2, pp. 15).—A collection of data pertaining to the feeding, care, and management of swine. Tables are given showing the estimated cost of feed for swine when fed different rations.

Breeds of hogs.—The best crops to grow for hogs, and other data, W. H. DALRYMple, W. R. DOBSON and S. E. McCLENDON (Louisiana Sta. Bull. 121, pp. 56, figs. 24).—The characteristics of the razorback and improved breeds of hogs are described, and details are given for growing and harvesting crops which are recommended for hogs. Other topics treated are rotation of crops for hogs, portable fences, breeding crates, the Schuler methods of curing pork on the farm, and the State regulation concerning the importation of hogs.

Spanish peanuts, dwarf Essex rape, and cowpeas for swine, P. N. FLINT (Arkansas Sta. Circ. 5, pp. 4).—The feeding value for swine of these crops is discussed, and methods are given for growing them.

Feeding experiments with dried beer yeast, O. R. VON CZADEK (Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 3, pp. 214-231).—Somewhat faster gains were made when yeast was added to potatoes and bran in rations for swine. Analyses of the feeds, urine, and feces are given.

Hog houses, J. A. WARREN (U. S. Dept. Agr., Farmers’ Bul. 438, pp. 29, figs. 21).—This bulletin discusses the sanitary and economical housing of hogs. Several varieties of hog houses and hog cots are illustrated and described, showing both faulty construction and well-built types. Tables are given based on astronomical calculations showing the best location of windows in order to provide the maximum amount of sunshine in hog houses in any latitude of the United States.
Fattening turkeys (Landw. Umschau, 1910, No. 44, p. 1087; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Inst. and Plant Diseases, 1910, No. 2, p. 319).—Methods of fattening turkeys in Germany are described, as comprising, "in the morning, barley meal, slightly cooked wheat bran, maize which has been soaked in water, and boiled potatoes; at midday and in the evening, wheat and oats. Oats are considered excellent food. The birds are allowed free pasturage."

DAIRY FARMING—DAIRYING.

Trial of soy-bean cake. J. Mackintosh and W. Goodwin (Jour. Southeast. Agr. Coll. Wye, 1909, No. 18, pp. 225–239).—Soy-bean cake was found to be a palatable food for milch cows, and when fed to the extent of 3 pounds per head per day in connection with other foods it had no noticeable effect on the quantity or quality of the milk produced or on the flavor, color, or consistency of the butter.

The home of the large red dairy breed of north Schleswig, R. Georges (Decu. Landw. Tierzucht, 15 (1911), No. 12, pp. 137–142; figs. 8).—A general and statistical article, which treats of this breed and methods of breeding, feeding and management, and gives data on milk production.

The Sardinian sheep is the most popular breed, but a year after exportation the milk flow decreases, and they are no longer remunerative. By crossing with the Barbary sheep a breed is obtained which maintains a better flow of milk and which is superior to the imported sheep in the yield of wool and meat, the cross producing 2 kg. of wool per year, and from 18 to 20 kg. of meat.

The action of infundibulin upon the mammary secretion, I. Ott and J. C. Scott (Proc. Soc. Expt. Biol. and Med., 8 (1910), No. 2, pp. 48, 49).—In the case of a goat infundibulin (the active principle of the posterior part of the hypophysis), when injected into the vein of the ear, rapidly and greatly increased the secretion of milk in the early nursing period.

The galactagogue action of the thymus and corpus luteum, I. Ott and J. C. Scott (Proc. Soc. Expt. Biol. and Med., 8 (1910), No. 2, p. 49).—"In experiments upon the goat with the glands containing internal secretions, we have found the corpus luteum, pineal body and thymus increased the quantity of milk fourfold in 5 minutes. The ovary minus corpus luteum had no effect. Infundibulin is still the most powerful galactagogue, increasing the secretion of milk one-hundredfold. The amount of butter fat was about the same in the augmented secretion by thymus, corpus luteum, and infundibulin, but occasionally it was increased."

Investigations on the colostral milk of the cow, the goat, and the sheep, E. Weber (Milch, Ztg., 39 (1910), Nos. 10, pp. 433–439; 11, pp. 481–492; 12, pp. 543–563).—The literature on the subject is reviewed, and the author presents a large amount of data obtained from his own investigations on the physical and chemical properties of colostrum.

A bibliography of 104 titles is appended.

Studies on sheep's milk, A. Burr and F. M. Berberich (Milch, Ztg., 39 (1910), No. 52, pp. 613–617; 49 (1911), Nos. 10, pp. 95–97; 11, pp. 105–107; 12,
pp. 115–117).—A continuation of earlier work (E. S. R., 23, p. 582), with a description of products made from sheep's milk, especially the methods of manufacturing cheese in Italy, France, Portugal, and Germany.

Variations in the amount of fat in milk due to variations in the times of milking, S. H. Collins (Proc. Univ. Durham Phil. Soc., 4 (1910–11), No. 1, pp. 35, 36).—The author has coordinated the data obtained the last few years by the agricultural departments of colleges and county councils upon the composition of milk at different intervals, with the following results:

"When the intervals between milking are about 12 and 12 hours, for example cows milked at 6 a.m. and 6 p.m., then the morning fat exceeds evening fat by 0.18 per cent on the average of 22 tests. When the intervals between milking are about 13 and 11 hours, for example cows milked at 6 a.m. and 5 p.m., then the evening fat exceeds morning fat by 0.53 per cent on the average of 192 tests. When the intervals between milking are about 14 and 10 hours, for example cows milked at 6 a.m. and 4 p.m., then the evening fat exceeds morning fat by 0.70 per cent on the average of 18 tests. When the intervals between milking are about 14½ and 9½ hours, for example cows milked at 6 a.m. and 3:30 p.m., then the evening fat exceeds morning fat by 1.69 per cent on the average of 301 tests."

Variations in the coagulating quality of milk in individual herds, H. Höft (Milchkr. Zeitschr., 6 (1910), No. 12, pp. 533–536).—The chemical constants of the milk of 2 herds of cows are reported. The variations in the ability to coagulate milk with 3 different rennets are presented in tabular form.

The chemical composition of milk in the eastern districts of the Cape Province, J. Muller (Agr. Jour. Union So. Africa, 1 (1911), No. 2, pp. 194–198).—A summary is presented of analytical data obtained between the years 1903 and 1910. The average analysis of 437 samples of milk made during the period was fat 4.37, total solids 13.34, and specific gravity 1.0318.

Cooperative herd testing, W. D. Saunders and C. W. Holdaway (Virginia Sta. Bul. 190, pp. 3–30, figs. 14).—A study of 5 herds supplying milk to the college creamery, comprising 70 grade cows, only about half of which could be considered a good dairy type.

The average milk production was 4,113 lbs., having an average of 180.2 lbs. of milk fat. The average net profit was $23.35 after deducting the estimated cost of food and labor and crediting the estimated value of the manure. Only 4 per cent of the cows gave a net profit of $50, and but 34 per cent a profit of $30. Four per cent were kept at an actual loss to the owner.

The monthly totals showed that all the winter cows dropped in their milk considerably after the first month from calving. The milk flow was increased when returned to pasture. In the college herd a ration was fed which kept the milk flow up to a fairly uniform standard during the whole winter, so that when the cows were turned out on grass there was no increase. The estimated loss during the winter from inadequate feeding in 3 herds comprising 26 cows is estimated at $143.50, or a total loss of $5.52 per cow.

It is thought that these results may be taken as representative of the conditions existing in most sections of Virginia. It is recommended that records of individual cows be kept so that the "robber" cows may be detected and eliminated from the herd.

Inquiry into methods of sampling milk (Jour. Bd. Agr. [London], 13 (1911), No. 1, pp. 30–36).—The results of a study of the efficacy of the various methods of sampling were as follows: (1) The tube method was ineffective, (2) the dipper method failed to insure in every case efficient mixing, (3) the plunger method gave results only slightly inferior to those obtained by the thorough method adopted in taking the control sample, and (4) the pouring
method (pouring into an empty vessel and back again 3 times) was found to mix the milk effectively.

On the knowledge and nomenclature of bacteria found in milk and its products, F. Löhnis (*Zeitbl. Bakt. [etc.], 2. Abt., 29 (1911), No. 12-14, pp. 331-340*).—A résumé of recent work to show the interrelationships of the common species of milk bacteria.

Contribution to the question of cooling milk, W. Pies (*Milchw. Zeitbl., 6 (1910), No. 12, pp. 537-540*).—The author reports that when milk was cooled quickly to a temperature of 4° C. bacteria multiplied more rapidly the first 24 hours than when it was cooled slowly.

"Of 18 children who drank milk in which tubercle bacilli were demonstrated, all but one remained free from active tuberculosis during a period of supervision of 3 years; this one developed tuberculosis of the cervical glands, from which a bacillus of the bovine type was cultivated.

"From animal experiments we can conclude that the chance of infection through milk depends not only on the number of bacilli ingested, but also on the frequency of exposure to small infections. For a quantity of bacilli which was insufficient to produce tuberculosis in guinea pigs when given in 1 dose, suspended in milk, was able to incite tuberculosis when fed in 25 to 30 doses on as many days.

"Tubercle bacilli in milk are a menace to the health of young children. Tubercle bacilli in butter are likewise a menace; therefore, a safe butter, whether pasteurized or certified, should be provided for their use."

Care of cream on the farm, F. A. Jorgensen (*Illinois Sta. Circ. 148, pp. 12, figs. 6*).—The object of this circular is to point out the causes for the poor grade of much hand-separated cream, and to illustrate methods of arranging a place at small cost where cream may be properly kept on the farm. Directions are given for washing the separator, and methods of cooling the milk.

Farm butter making, C. H. Tourgee (*Arkansas Sta. Circ. 6, pp. 4*).—This contains practical information as to the care of milk and making butter on the farm.

An ingenious cow stall (*Country Gent., 76 (1911), No. 3036, p. 342, figs. 6*).—A new type of sanitary cow stall is illustrated and described. The stalls can be washed out, and in place of a manger there is a feed pan which can be easily cleaned and when not in use is swung back on a gate in front of the cow.

**VETERINARY MEDICINE.**

Veterinary parasitology, R. H. Smythe (*London, 1911, pp. XIV+129, figs. 29*).—This is a small compend prepared for use in veterinary schools.

Technique of sterilization, E. Gérard (*Technique de Stérilisation, Paris, 1911, 2. ed., rev. and enl., pp. VII+352, figs. 72*).—After discussing the general principles underlying sterilization, the book treats of general methods of sterilization, sterilization of glassware, surgical instruments, water, oils, fats, drugs, ampuls, surgical dressings, ligatures (and their preparation), drains, sounds, bougies, rubber gloves, and milk (human, cow's, and homogenized), the disinfec-
tion of rooms, books, clothes, etc., and the disinfection of water with ultraviolet rays.

The biological standardization of drugs, W. Hale (Amer. Jour. Pharm., 33 (1911), No. 3, pp. 97-111).—This article considers the various methods utilized for standardizing drugs, but has particular reference to digitalis, strophanthus, and ergot.

In regard to the reaction of the urine from domestic animals, H. Müller (Beiträge zur Reaktion des Haras der Haussäugetiere. Inaug. Diss., Giessen, 1910, pp. 35; abs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 5 (1910), No 22, p. 857).—The urine of carnivorous animals, according to the author, is not as often acid in reaction as is generally supposed.

In the case of starved animals the urine is not characterized by acidity, nor do carnivorous animals which are fed on a vegetable diet necessarily yield a urine alkaline in reaction. It was found, however, that the reaction of the urine from herbivorous animals can be changed much quicker than that of carnivorous animals. Carnivorous animals affected with cystitis yield an alkaline urine, while herbivorous animals having marked affections of the alimentary tract, pharyngitis, pneumonia, or muscular rheumatism, yield an acid urine.

Diaz reaction of the urine of domestic animals, A. Janssen (Über Diazoreaktionen bei Haustieren. Inaug. Diss., Giessen, 1910, pp. 29; abs. in Zentbl. Gesam. Physiol. u. Path. Stoffwechsels, n. ser., 5 (1910), No 22, p. 858).—The diazo reaction of the urine, according to the author, does not appear so constantly in animals as it does in man, but where it is present it has the same significance. It was not present in most of the febrile diseases of domestic animals. As in man, the reaction can be obtained when administering certain drugs.

Some experiments on the solubility of gases in ox blood and ox serum, A. Findlay and H. J. M. Creighton (Bio-Chem. Jour., 5 (1911), No. 6-7, pp. 294-305, figs. 5).—"The solubility of oxygen, carbon dioxide, carbon monoxide, nitrous oxide, and nitrogen in ox blood and ox serum has been determined at a temperature of 25° and under pressures varying from 750 to 1,400 mm. The solubility of oxygen, carbon monoxide, and carbon dioxide in blood, and of carbon dioxide in serum, is greater than in water; the solubility of nitrogen and nitrous oxide in blood and in serum, and of oxygen and carbon monoxide in serum, is less than in water. Where the solubility is increased, the solubility curves fall with increasing pressure; where the solubility is diminished, the solubility curve rises with increase of pressure. The increased absorption of oxygen, carbon monoxide, and carbon dioxide in blood, and of carbon dioxide in serum, is to be ascribed in the main to chemical combination. In the cases of diminished solubility, the rise in the solubility curve is to be ascribed to adsorption."

Peptolytic substances and immune bodies in the blood, G. B. Gruber (Ztschr. Immunitätsf. u. Exptl. Ther., I, Orig., 7 (1910), No. 6, pp. 762-777, figs. 4).—The results show that by injecting proteins the production of peptolytic bodies in the blood serum which have no relation to the hemoglobin is induced. Precipitins, hemolysins, and agglutinins are produced independent of the peptolytic ferment. Peptolytic ferments and immune bodies can occur at the same time, but are distinctly different substances. The results further show that peptolytic ferments occur in markedly emaciated rabbits, even when no injections of proteins are made or when the animal is treated with trypanosomes. Peptolytic substances also occur when the animal is required to take protein foods in different forms than it has been in the habit of taking. Peptolytic ferments further occur in cachectic human patients afflicted with tumors.
EXPERIMENT STATION RECORD.

Hemolysins, cytotoxins, and precipitins. A. von Wassermann (Hämolyssine, Zytotocinc und Präzipitine. Leipzig, 1910, rev. and ent. ed., pp. 124).—This is a revised and enlarged edition of this work, which deals with the hemolysins of blood serum. Hemolysins of normal serum, isohemolysins and autohemolysins, amboceptors, complements, antihemolysins, complement binding, hemaglutinins, and the practical significance of the hemolysins are discussed by J. Leuchs, and cytotoxins and precipitins by M. Wassermann.

The influence of the reaction on the activity of hemolytic sera, P. Rondoni (Ztschr. Immunitätsf. u. Exptl. Ther., I, Orig., 7 (1910), No. 5, pp. 515–545).—The results indicate that hemolysis and amboceptor formation can be inhibited under certain conditions by sodium hydrate. Hydrochloric acid, on the other hand, stimulates hemolysis but inhibits amboceptor formation, though to a lesser degree than alkali.

In regard to the methods used for detecting leucocytic bactericidal substances, A. Pettersson (Ztschr. Immunitätsf. u. Exptl. Ther., I, Orig., 7 (1910), No. 6, pp. 693–701).—Contrary to the opinion of some that the leucocytes attack only dead or dying bacteria, the author finds that the leucocytes in the animal body are capable of destroying bacteria which have the capacity to propagate. He points out, further, that the negative results which are obtained in vitro do not warrant the conclusion that no bactericidal capacity exists, even in vivo.

Guinea pig leucocytes were capable of destroying Bacillus subtilis without the aid of the serum.

About the theory of phagocytosis, I. G. Sawtchenko and V. A. Barrykine (Arch. Sci. Biol. [St. Petersb.], 15 (1910), No. 5, pp. 418–427).—Only an alexin of the same origin as the leucocyte favors phagocytosis. The alexins of other species (except those of the horse) have a more or less inhibitory reaction.

"That this is not referable to a difference in structure of amboceptor and complement in man and in the lower animals the author regards as proved by the following findings: Among a number of strains of streptococc, virulent for man, more were found to be virulent also for animals than in a corresponding number of strains nonvirulent for man; mice were protected by a potent human immune serum quite as well as by rabbit or horse serum. A potent immune serum was successfully obtained from monkeys only in those cases in which the animals survived a severe infection induced by repeated intravenous injections of large masses of living cocci.

"Local infection was found unfavorable to the development of immunity, and is to be regarded as a process differing essentially from the general systemic reaction, which possibly explains the fact that no immunity results from streptococcic infection in man. The author was able to obtain, however, in one case of severe streptococcosis, a serum which protected mice against a thousand-fold fatal dose of mouse-virulent streptococc. Normal serum, whether from the same or different species, not only did not protect animals but even hastened death. Injections of fresh normal human serum in man, on the other hand, appeared to have a favorable effect in most cases."

About the therapeutic value of beer yeast in staphylococcus and streptococcus infections, W. Walczow and G. Sacharow (Med. Obozr. [Moscow], 71 (1909), No. 10, pp. 936–942; abs. in Hyg. Rundschat, 20 (1910), No. 24, p. 1107).—The use of beer yeast raises the opsonic index in the above-mentioned
conditions. The repeated use of the yeast preparation confers a greater resistance against infection with the pus-producing organisms.

Bactericidal value of thymol, E. W. Schmidt (Ztschr. Physiol. Chem., 67 (1910), No. 6, pp. 412-33; abs. in Zentbl. Biochem. u. Biophys., 10 (1910), No. 17-18, p. 812).—Thymol did not prove entirely efficient for enzymological work. It is not of any value as an antiseptic or as a disinfectant with certain kinds of putrefactive bacteria, nor can it be employed as a disinfectant for digestion studies which employ an alkaline reaction and which extend over a long period of time.

A simple method for growing the meningococcus, R. Bruynoghe (Centbl. Bakl. [etc.], 1, Abt., Orig., 56 (1910), No. 1, pp. 92-94).—The method consists of adding the spinal fluid from the patient to an equal volume of bouillon, incubating for 24 hours at 37°C., and examining microscopically.

Researches in regard to Jenner's vaccination method, E. Huon (Rev. Gén. Méd., Vét., 16 (1910), No. 157-158, pp. 364-385, figs. 6, charts 2).—Regeneration of vaccine can be effectively accomplished by passing it through an ass. The technique employed and the results obtained with such vaccines are given.

Distillery slop disease (schlempenauke), Musterle (Münch. Tierärztl. Wchnschr., 54 (1910), No. 12, pp. 159-162; abs. in Berlin, Tierärztl. Wchnschr., 27 (1911), No. 6, p. 195).—The author observed in a cooperative bakery barn, where distillery slop disease (schlempenauke) often occurred, that the diluted slop mixed with roughage was allowed to stand for 12 hours before being fed. The feed during this time assumed a disagreeable, sour odor, and microscopically it showed myriads ofission fungi.

When the feed was scalded or boiled before being fed, no cases of this disease occurred over a period of 2 years.

Diagnosis of glanders with the aid of the complement deviation method, Schütz and Schubert (Arch. Wiss. u. Prak. Tierheilk., 35 (1909), No. 1-2, pp. 44-83, figs. 2).—This is a detailed description of the application of the complement deviation or fixation reaction to the diagnosis of glanders, as based on the phenomenon of hemolysis, first noted by Bordet and Gengou.

The diagnosis of glanders by complement fixation, J. R. Mohler and A. Eichhorn (U. S. Dept. Agr., Bur. Anim. Indus, Bul., 136, pp. 31, pls. 5).—The authors have in this bulletin given a detailed and practical description of the Schütz and Schubert complement fixation, complement deviation, or complement binding methods (see above) for the diagnosis of glanders.

The principles of hemolysis are explained, and the methods of obtaining the hemolytic amboceptor (rabbit serum) and the complement (guinea pig serum) and their titration are set forth. Specific complement fixation (deviation) is discussed, as well as the method of obtaining the serum of animals to be tested, the preparation of the antigen (glanders bacilli extract), and the titration of the extract. Data are given as to the application of the complement fixation test, use of controls, interpreting the results of tests, and controlling glanders in an infected stable. Results of practical tests with complement fixation are reported.

The authors point out that with a good-sized incubator and the apparatus mentioned in the bulletin it is possible for any laboratory to meet the demands for diagnoses of all the veterinarians within a State's borders, as from 80 to 100 tests may be readily made in one day.

"The agglutination test may be undertaken with the complement fixation test without a great deal of difficulty, especially if the agglutination test is carried out in accordance with the method used at the present time in Germany, by which the results of the test can be obtained in about 2 hours. This consists of a modification of the agglutination test, in which by centrifugalization the
agglutination is hastened in the test tubes and the results can be read after the tubes have been placed in the incubator for 2 hours."

In order to determine how long a time after infection elapses before the reaction appears positive, the authors infected a horse by rubbing a loopful of a virulent culture of glanders bacilli upon the Schneiderian membrane. Five days after the infection a positive reaction was obtained, although the animal did not show any clinical evidence of the disease.

The blood from 787 horses from the District of Columbia and other parts of the United States was examined with the test. Some of the horses were clinical cases of glanders, others were simply exposed or contact cases, while another group was selected because they gave atypical and typical reactions with mallein. The results showed that the complement binding or deviation test gave positive findings in 97 per cent of the glanders cases. It was also determined that in affected horses where atypical or negative results were obtained the cases were old chronic ones, or that they were fresh cases tested during the period of incubation. In all instances where the animals reacted positively and came to autopsy, lesions were noted in one or more of the organs. Among the horses tested there were also some animals which gave an atypical reaction to the mallein test, but on testing with the complement fixation test they yielded either a positive or a negative result.

According to the authors, "the results indicate that in the complement fixation we have a method which in accuracy is equal to the tuberculin test for the diagnosis of tuberculosis in cattle."

The diagnosis of glanders in the cadaver. F. P. Keyser (Die Diagnose des Kotzes am Kadaver. Inaug. Diss., Bern, 1910, pp. 82, pls 3; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 48 (1910), No. 8, pp. 244, 245) — As cases of occult glanders often occur and the disease is not detected before the animal is slaughtered, the author sought to determine which is the best method to detect this disease in the cadaver. On the basis of his findings he concludes that the guinea pig test and the agglutination test give doubtful results, while the complement-fixation reaction and the microscopic examination give a correct finding.

The elimination of glanders by the aid of the diagnostic blood examination, Schubert (Arch. Wiss. u. Prakt. Tierheilk., 35 (1910), Sup., pp. 611–628; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 48 (1910), No. 8, p. 248) — As a result of examining 3,283 horses for glanders with the complement-fixation and agglutination tests, among which number 124 reacted positively, the author reached the following conclusions:

1. If 0.1 cc. of a horse serum shows a complete deviation of complement the animal should be destroyed without regard to what the finding with the agglutination test may be; (2) if 0.1 cc. of the serum yields only an incomplete deviation, and 0.2 cc. produces a complete or incomplete reaction, the animal should be destroyed without regard to the finding with the agglutination test; (3) the serum of animals which do not react in amounts of 0.2 cc. should be killed only if there is an accompanying agglutination value of over 1,000; (4) horses in which the serum does not deviate with amounts of 0.2 cc., and which possess an agglutination value of not over 1,000 are to be treated as nonsuspected cases if the blood findings were obtained 14 days after the quarantine has been raised. If the blood findings were obtained less than 14 days before the quarantine was lifted, then a second blood examination is to be made 14 days after the first one, and if this yields the same results as the first one, the animals are to be considered as not diseased.

A comparison of the different methods of preparing hemorrhagic septicaemia vaccine and the immunizing value of old and new vaccine for hemor-
rhagic septicemia, F. S. H. Baldrey (Jour. Trop. Vet. Sci., 5 (1910), No. 4, pp. 592-594).—These experiments, which were conducted with bulls and rabbits, resulted in demonstrating that a vaccine for hemorrhagic septicemia should contain dead organisms only, and no broth toxin. The latter is excluded because it sets up an irritation which prolongs the negative phase and gives the animal unnecessary pain. A further test showed that after 10 months the hemorrhagic septicemia vaccine depreciated 50 per cent in value. The disease is very analogous to human plague.

Anaplasmosis in donkeys. A. Baldwin (Jour. Compar. Path. and Ther., 24 (1911), No. 1, pp. 47-47, fig. 1).—The author reports that in addition to cattle he has found marginal points to occur in large numbers in the blood of a number of donkeys in the Sudan, one of which was suffering from piroplasmosis. Rhipicephalus evertsi was found upon donkeys when they arrived in Khartum and the author is of the opinion that this tick will be found to convey the infection.

Some observations on the subject of marginal points, W. Jowett (Jour. Compar. Path. and Ther., 24 (1911), No. 1, pp. 40-44, figs. 2).—The author records the discovery of coccius-like bodies, or marginal points, in cats and rats, and also in blood films prepared from cases of equine piroplasmosis in Cape Colony.

Piroplasmosis in India, F. S. H. Baldrey (Jour. Trop. Vet. Sci., 5 (1910), No. 4, pp. 569-579, pl. 1, dysms. 3).—An account based on various reports made by officers of the veterinary department in India, is given. Attention is called to the fact that what appears to be the same species of Piroplasma as that recently described by Patton as P. gibsoni (E. S. R., 23, p. 792) was described in 1903 by Lingard as P. tropicus.

A list of 33 titles referred to is appended.

Atoxyl in the treatment of bovine and ovine piroplasmosis, Udrisky (Arhiva Vct., 7 (1910), No. 4, pp. 223-227).—Sheep suffering from piroplasmosis received 6 doses of 200 mg. of atoxyl (in 10 cc. of distilled water) subcutaneously in 2 series of 3 consecutive days, separated by an interval of 1 day. But 1 of 11 full-grown sheep treated in this manner succumbed to the disease, and as favorable results followed the administration, in a similar manner, of 1 or 1 or 1/4 gm. of atoxyl to bovines.

A contribution on the treatment of canine piroplasmosis with trypanblue, H. Rumann (Ztschr. Hyyg. u. Infektionskrank., 67 (1910), No. 2, pp. 201-224, figs. 13).—A brief review of the literature relating to the use of this dye is followed by a report of experiments personally conducted.

The paper includes a bibliography of 29 titles.

Canine piroplasmosis in Russia, W. L. Yakimoff (Bul. Soc. Path. Ecol., 4 (1911), No. 2, pp. 110-112).—The author reports the occurrence of piroplasmosis in a dog at St. Petersburg. In inoculation experiments with 14 dogs the incubation period was found to vary from 2 to 7 days.

Immunizing cattle against anticattle-plague serum, E. H. Ruediger (Philippine Jour. Sci., B. Med. Sci., 4 (1909), No. 5, pp. 353-361, charts 9).—"Apparently anticattle-plague serum, when repeatedly injected under the skin of healthy, nonimmune bullocks, does not lead to the production of anti-immune bodies. The more serum injected into an animal the milder is the attack of cattle plague which follows inoculation with virulent blood. In this respect the immunity reactions in cattle plague are similar to those observed in many infections of known bacterial origin."

Immunizing against streptococcic infection, with particular reference to strangles, A. Marxer (Ztschr. Infektionskrank. u. Hyg. Hautiere, 8 (1910), No. 4-5, pp. 322-346; abs. in Zentbl. Biochem. u. Biophys., 11 (1910), No. 1,
By immunizing rabbits against streptococcoc infection the author found that the bacteria for preparing the vaccines which were killed with urea or galactose solution were more efficient than those killed by heat. It was found that one strain of the vaccine bacteria is antagonistic to other strains of bacteria. A monovalent serum protects in the same manner. An antistreptococcoc serum prepared from streptococcus obtained from cases not having strangles was efficient for strangles. The serum from horses which recovered from strangles contained practically no protective bodies.

Protective and curative vaccination against tetanus, Schuemacher (Mitt. Ver. Bad. Tierärzte, 10 (1910), No. 5, pp. 75, 76; abs. in Berlin, Tierärztl. Wochenschr., 27 (1911), No. 6, p. 105).—Many cases of tetanus occurred in unvaccinated horses, whereas animals vaccinated biyearly with 10 cc. of Pasteur’s antitetanic serum never took the disease. Two cases of severe tetanus were treated subcutaneously and successfully with 50 cc. of this serum on the first day, 30 cc. on the second day, and 20 cc. on the third day. Another animal which was treated at a late hour died.

In regard to tuberculosis infection and its virus, A. Fontes (Mem. Inst. Oswaldo Cruz, 2 (1910), No. 1, pp. 141-146).—As a result of his work with filtered tuberculous pus the author considers the granulations in the tubercle bacillus the living and infective factor of the organism. It is further stated that certain typical clinical cases which yield negative results for the tubercle bacillus with the usual staining methods can be explained by the presence of these granulations in the body, as the granulations can eventually develop into tubercle bacilli.

In regard to the biology of the tubercle bacillus, H. Aronson (Berlin. Klin. Wochenschr., 37 (1910), No. 35, pp. 1517-1620; abs. in Chem. Zentral., 1910, II, No. 19, pp. 1591, 1592).—The specific staining power of the tubercle bacillus is due to the presence of a wax, which, according to the author, contains an alcohol which is not cholesterol. The wax can be absolutely extracted with trichlorethylene, which at the same time extracts Much’s granule. According to this finding the latter can not consist of a particular form of protein. The solvent action of neurin for tubercle bacilli, according to the author, is due to strongly alkaline properties which the bodies have, which belong to the neurin class. The solution can also be made with tetramethyl ammonium hydrate. See also a note by Lindeman (E. S. R., 24, p. 283).

A new method for the cultural and microscopic detection of the tubercle bacillus in sputum and other tuberculous material, Uhlenhuth and Kersten (Ztschr. Exp1. Path. u. Thcr., 6 (1909), No. 3, pp. 759-776).—The method consists of placing the sputum in a 15 per cent antiformin solution in a large sterile Drigalski dish which sits on a dark background. After the sputum has become liquefied the remaining flocculent masses are fished out with a platinum loop and placed in a physiological salt solution to remove the adherent antiformin. The mass is then carefully rubbed up with solidified glycerin bovine serum (6 to 8 tubes), the cotton plugs of the tubes flamed, and sealed with paraffin.

The method furnishes very good results.

Inhalation and feeding tests with tubercle bacilli and bovines to determine the smallest possible amount necessary for infection, A. Weber and C. Titze (Tuberkulose Arb. K. Gsundheitsamt., 1910, No. 10, pp. 146-150).—The tests showed that at least 0.00001 gm. by inhalation and 0.01 gm. per mouth of tubercle bacilli are necessary to infect bovines.

Open-air experiments with tuberculous cattle, J. G. Rutherford (Amer. Vet. Rev., 38 (1910), No. 3, pp. 313-349).—The author, after slaughtering all clinical cases of tuberculosis in a herd, observed the 42 survivors for some
time. The points which he tried to elicit were "(1) to ascertain the effects of the open-air treatment on the diseased cattle themselves, (2) to ascertain to what extent healthy cattle kept in contact with diseased cattle were subject to infection, and (3) to ascertain what percentage of healthy calves it is possible to rear without any precautions from diseased cows kept under open-air conditions.

"The evidence on the whole leads to the conclusion that open-air treatment is not likely to exercise any marked curative influence on animals already tuberculous, especially when reinfection is possible through cohabitation with clinical cases. . . . The proportion of healthy calves raised from the whole herd, namely 60 per cent, is at first sight somewhat discouraging, but when it is remembered that, with one exception, all the cows on which they were reared were affected with tuberculosis, that one had a tuberculous udder, and that a number of the others were open and clinical cases, the matter assumes a somewhat different aspect. The author believes it highly improbable that such a large percentage of healthy calves could have been obtained from a herd of the same kind under ordinary stable conditions."

Should renal tuberculosis be reckoned amongst the open conditions? KALLINA (Arch. Wiss. u. Prakt. Tierheilk., 36 (1910), No. 2, pp. 137-176, pl. I; abs. in Berlin, Tierärztl. Wehnschr., 27 (1911), No. 6, p. 104.)—Renal tuberculosis, according to the author, should be considered an open condition. The difficulty of obtaining urine samples for diagnostic purposes is pointed out.

About the tuberculin testing of cows furnishing milk for infant feeding, C. BOLLE (Berlin, Klin. Wehnschr., 47 (1910), No. 26, pp. 1227-1228; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 4 (1910), No. 10, p. 314.)—The author details his findings with 304 cows in a dairy herd which furnished milk for infant feeding purposes. In no instance was open tuberculosis present. The milk from 75 cows which reacted positively was injected into guinea pigs, with the result that only one guinea pig became tuberculous. The milk from 9 of the cows on injection produced doubtful results in 2 guinea pigs, but the rest were negative.

The author, on the strength of the above results, points out the uncertainty of the tuberculin reaction in so far that with the same animals it at times gives positive results and at other times negative results.

Tuberculin testing of cows yielding milk for infant feeding purposes, B. MöLLERS (Berlin, Klin. Wehnschr., 47 (1910), No. 26, pp. 1228-1230; abs. in Ztschr. Immunitätsf. u. Expt. Ther., 11, Ref., 3 (1910), No. 1, p. 539.)—The author considers that the clinical and bacteriological examination can not displace the tuberculin test, and therefore the latter must still be the chief factor in judging milk for infant feeding purposes.

Investigations in regard to tuberculin, A. WEBER and DIETERLEN (Tuberkulose Arb. K. Gsnidtsamt., 1910, No. 10, pp. 217-220.)—This work has to do with comparative studies of the tuberculin prepared from human and bovine tubercle bacilli and the detection of the antibodies against the tuberculin in the serum of tubercular and nontubercular animals, and the question of the specific action of tuberculin given per alimentary tract.

In regard to the complement binding substances in the serum of tubercular children, R. FUA and H. KOCHE (Beitr. Klinik Tuberkulose, 14 (1909), No. 1, pp. 79-86; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 4 (1910), No. 11, p. 565.)—The serum from subjects treated with tuberculin contained complement binding substances, while untreated cases did not.

Kimmer's method for vaccinating against tuberculosis. A. WEBER and C. TITZE (Tuberkulose Arb. K. Gsnidtsamt., 1910, No. 10, pp. 200-216.)—The re-
suits of the tests were generally unsatisfactory. See also a previous note (E. S. R., 22, p. 186).

A catechism on bovine tuberculosis, H. L. Russell and E. G. Hastings (Wisconsin Sta. Ciric. Inform. 23, pp. 24, figs. 8).—This circular, arranged in the form of a catechism, is designed for use by those desiring information on tuberculosis, its cause, effect, and mode of distribution, the mode of application and interpretation of the tuberculin test, and tuberculosis control.

Experimental studies in regard to the etiology of tumors, S. Löwenstein (Beitr. Klin. Chirurg., 69 (1910). No. 3, pp. 623-700, pls. 1, figs. 3; abs. in Zentral. Biochem. u. Biophys., 11 (1910), No. 1, pp. 14, 15).—If inflammation and swelling are present, epithelial cysts can be produced experimentally. They do not possess a progressive character, and, therefore, do not conform to the Cohnheim-Ribbert theory.

The author was also able to produce hemorrhages in the bladder, such as occur in papilloma of the bladder, by injections of benzidin.

About the antigenic properties of tumor lipoids, G. Izar (Ztschr. Immunität'sf. u. Exp. Thcr., 1, Orig., 7 (1910), No. 5, pp. 624-628).—The activity of megatheriolysin increases up to 55° C., after which it decreases until 70° is reached. At 75° the activity again increases until the boiling point is reached.

The technique of the meistostagmin reaction with malignant tumors, M. Ascoli and G. Izar (München. Med. Wechschr., 57 (1911), No. 41, pp. 2129-2131; abs. in Chem. Abs., 5 (1911), No. 2, p. 329).—The powdered tumor is macerated for 24 hours with methyl alcohol at 50° C., shaking occasionally during the period. The mixture is filtered off hot, cooled, and filtered again. The antigen is prepared as usual—0.1 cc. of a 1:100 to 1:200 aqueous emulsion to 9 cc. of the serum, which has been previously diluted 20 times with 0.85 per cent sodium chloride solution. The influence of different acids and salts on the reaction are noted. See also a previous note (E. S. R., 24, p. 780).

The meistostagmin reaction in foot-and-mouth disease, A. Ascoli (Deut. Med. Wechschr., 36 (1910), No. 43, pp. 1997-1999; abs. in Chem. Abs., 5 (1911), No. 2, p. 329).—When a specific antigen (virus) was added to the blood serum of animals having foot-and-mouth disease, an increase in the surface tension of the serum was noted. This was greater than when the same addition was made to normal serum. The positive reaction is present some time after recovery from the disease.

Some diseases of swine, N. S. Mayo (Virginia Sta. Bul, 189, pp. 3-19, figs. 6).—Following a brief account of simple sanitary precautions and inexpensive shelter houses, the author discusses swine mange, swine lice (Haematopius suis), "bull nose" or necrotic stomatitis, chronic pneumonia or coughing, hog cholera, and paralysis in swine, including preventive measures and remedies.

[Note on a nematode from the stomach of the pig], Foster (Abs. in Science, u. scr., 33 (1911), No. 550, pp. 590, 591).—Notes are presented on the occurrence of Spirulera strongylina (or a new species) in the United States. A second species (Physoccephalus sexalatus) that was found associated with S. strongylina is recorded from the United States for the first time and this is also said to be the first record of its occurrence in the domestic pig.

Is there any danger of disseminating hog erysipelas by immunizing with cultures of the organism causing this disease? W. Pirtt (Berlin. Tierärztl. Wechschr., 27 (1911), No. 6, pp. 98-103).—This is a polemical article, in which the author states that Rickmann's conclusions a in regard to Lorenz's serum-

bacteria simultaneous method (E. S. R., 8 p. 525) are not warranted. He accompanies his argument with statistics in regard to hog erysipelas for quite a number of years.

Trichinosis in the cat. J. Ciurea (Ztschr. Fleisch u. Milchhyg., 21 (1911), No. 6, pp. 171, 172; abs. in Jour. Comp. Path. and Ther., 21 (1911), No. 1, pp. 83, 84).—This is a report of a case of trichinosis in a cat in Roumania that apparently became infected with trichinae through feeding on rats. The infection appeared to be one of long standing.

Fowl spirochetosis. W. Jowett (Agr. Jour. Cape Good Hope, 37 (1910), No. 6, pp. 662-670, pl. 1, figs. 2).—The author records the occurrence of this disease in the vicinity of Cape Town.

RURAL ECONOMICS.

The possibilities of agriculture in Ohio, C. E. Thorne (Agr. Student, 17 (1911), No. 5, pp. 7-9, 34, 35).—This article points out that now the free lands of the Northwest are exhausted and the migratory movement which was steadily westward for several years has practically reached its culmination, the possibilities of agriculture in the East and Middle West are being considered more carefully than ever before. The water route advantages and the several transcontinental railway systems in Ohio "offer facilities for transportation not excelled by any similar area in the world," and since more than one-half its people live in large towns and cities and are largely occupied in manufacturing industries there are excellent local markets for farm produce.

The following table illustrates the progress of agriculture in Wayne County from 1851 to 1908:

<table>
<thead>
<tr>
<th>Period</th>
<th>Area in crops</th>
<th>Number of cattle</th>
<th>Ratio of cattle to crop acreage</th>
<th>Cost of fertilizer</th>
<th>Yield per acre</th>

While these figures show that there has been a general increase in the yield. It is recalled that the Ohio Station by a series of systematic experiments showed that "on a tract of 40 acres, farmed in a 4-year rotation of corn, oats, wheat, and clover, the yield of corn has been increased to a 5-year average of 70 bushels per acre; that of oats to 55 bushels; that of wheat to 36½ bushels, and that of hay to 4 tons."

A system of tenant farming and its results, J. W. Froley and C. B. Smith (U. S. Dept. Agr., Farmers’ Bul, 437, pp. 20).—This bulletin discusses the fundamental principles of a system of tenant farming, showing its advantages and disadvantages and why tenant farms often deteriorate.

Special attention is directed to a system of farming in eastern Maryland organized by a merchant with no special knowledge of agriculture, a system which has maintained for over 30 years yields sufficient to keep buildings, fences, etc., in a state of good repair and pay a net income of more than 5 per cent to the estate, and at the same time give satisfactory profits to the tenants.
The account shows 56 farms on this estate and discusses the cropping system employed, terms of rental, management of live stock, relation of the farming system to fertility, value of the system, its distinctive features and its possible improvement.

Estimating rent (In *Stephen's Book of the Farm*. *Edinburgh and London*, 1908, vol. 1, 5, ed., rev., pp. 267-270).—The author discusses the theories and gives illustrations of different methods of determining rents, showing that all land can not be valued on the same basis because of the diversification of production. Usually the rent is estimated according to the condition of the land at the time, but in some instances an estimated interest is allowed on improvements in addition to that paid for "the indestructible resources of the soil."

Survey and record of agricultural land in the Netherlands, C. W. Hoffmann (*Verslag. en Meded. Dir. Landb. Dept. Landb., Nijv. en Handel*, 1910, No. 6, pp. 33-85).—The article gives a detailed history of registers or surveys of real estate, for the purpose of determining a basis of taxation, in the Netherlands for more than a century, and discusses and illustrates fully the methods of registering and recording, and the extent, ownership, value of lands, mortgages, and all other records pertaining to real estate.

Small holdings (*Jour. Roy. Soc. Arts*, 59 (1911), No. 3048, p. 571).—The author points out some of the defects in the small holdings act and intimates that it has been only a qualified success. In 1895 there were 299,378 holders of parcels between 1 and 50 acres in England and Wales, and in 1900 the number had fallen to 288,011. Since the passage of the act only 519 applicants out of 22,455 have expressed a wish to buy the land. It is shown that this is not due to a lack of desire to purchase but for want of necessary capital for purchase and stocking. It is pointed out that the act is deficient in that it does not facilitate purchases.

Cooperative credit banks, H. W. Wolff (*Dairy*, 23 (1911), No. 268, pp. 93, 94).—This paper discusses cooperative credit banking as it is carried on in some foreign countries and shows by comparison the stimulus it would give to agriculture, commerce, and trade in the United States. It is claimed that the system has much to commend it, since it keeps at home the money produced in a locality and enables even the smallest producer or tradesman to obtain credit on security not recognized by existing institutions.

It is held that in addition to satisfying an economic want in Germany by providing enormous sums of money, these banks have had a powerful moral influence upon their members.

It is shown that the rural societies constitute 98 per cent of the whole number, which has more than doubled within the last year, and the working capital has increased in nearly the same proportion. Deposits from nonmembers have increased 350 per cent and loans have increased nearly 140 per cent. The actual working of the rural societies and the success or failure of each is discussed in detail.

Legislation and state intervention in regard to agricultural insurance (*Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intel.*, 2 (1911), No. 1, pp. 189-196).—This article discusses the general effects of legislation and state intervention in regard to agricultural insurance in France, giving statistical tables showing the progress made in cattle insurance in 1909, and a sketch of the results obtained by the insurance societies against hail in 1910.
There were 42,511 cattle insured in 1909 valued at 41,613,763 francs. The amount of loss was 2,659,786 francs, leaving a reserve of 709,233 francs.

Measures proposed for the regulation of the grain trade, with the assistance of the Zemstvo and the agricultural cooperative societies (Internat. Inst. Agr. [Rom], Bul. Bur. Econ. and Soc. Intel., 2 (1911), No. 1, pp. 99–106).—This article discusses the problems of marketing or exporting the agricultural products of the small farms in Russia.

It is shown that the farmer is compelled to sell his grain as soon as harvested in order to pay his debts, and that agents of foreign houses take advantage of this necessity to compel him to sell under the most disadvantageous conditions. The problem has been partially solved in some of the provinces by the establishment of cooperative societies and the starting of special corn warehouses where the peasants deposit their grain as security and receive loans from the society. This enables them to seek the best market for their produce. In some of the provinces the societies have established direct relations with foreign markets thus eliminating a large number of small speculators as middlemen.

General uplift and increase of agricultural labor by cooperative means (Wien ur Landw. Ztg., 69 (1910). No. 69, p. 711).—A speech delivered at the Twenty-Fourth Meeting of the German Agricultural Association in which are discussed the social and economic advantages of organized effort among agricultural laborers. It is suggested that it would tend to prevent the migration of agricultural labor and be of vast economic value to the agricultural industry of the country at large if each family of laborers should be allotted for a long term a small holding which it could call home and be given an opportunity of eventually paying for.

Farm servants and wages (In Stephen's Book of the Farm. Edinburgh and London, 1908, vol. 1, 5, ed., rev., pp. 289–294).—The author discusses in a general way the important element of farm labor in agricultural economy, showing the general effect of increased wages upon the standard of living in the British Isles from 1850 to 1900, and the different methods of employing laborers, together with tables which show the average earnings per week in various localities in England, Wales, Scotland, and Ireland, and the variation in wages, perquisites, and farm hours in each. The following table indicates the course of wages on a large number of farms in England, Scotland, and Ireland between 1850 and 1903, the rates being expressed as percentages of those for the year 1800, which is taken as 100:

Relative rise in wages since 1850.

Crop Reporter (U. S. Dept. Agr., Bur. Statis. Crop Reporter, 13 (1911), No. 4, pp. 25–32).—Statistics are given showing the condition and acreage of crops in the United States and foreign countries; the farm values and range of prices of important agricultural products; the condition of farm animals April 1, and
estimated losses during the preceding year; cotton production comparisons in the United States; data on the cost of producing corn in 1909; and monthly receipts and stocks of eggs and poultry in the United States.

Agricultural statistics of India for the years 1904-5 to 1908-9 (Agr. Statis. India, 25 (1904-1905). I. pp. III+392).—These agricultural statistics of India from 1904-5 to 1908-9 show the area under the various crops in the different provinces and the average yield of the principal crops, together with tables showing the incidence of the land revenue assessment on the area and population, and transfers of land.

Handbook of conservation, Mary L. Tucker (Boston, 1911, pp. VIII+91).—The author, who is chairman of the conservation department of the Massachusetts State Federation of Women's Clubs, presents a series of suggested topics upon the conservation of natural resources as a guide to club and classroom study and furnishes explanatory comments upon many phases of the subject.

AGRICULTURAL EDUCATION.

Agricultural education (Farmer's Guide, 23 (1911), No. 16, p. 510).—A brief outline is here given of the evolution of agricultural teaching in the United States from 1735 to 1857. The article also contains information concerning the growth of agricultural schools in Europe from the founding of a school at Hofwyl, Switzerland, in 1806, to the establishment of the Royal Agricultural College of England in 1845.

Vocational education, A. D. Dean (N. Y. State Ed. Dept. Bul. 479, 1910, pp. 191-208).—As an introduction to the review of laws relating to agriculture, manual training, and household economies, passed in 1907 and 1908 by the several state legislatures, the author discusses and defines the scope and purpose of vocational education. He states clearly that such education should be adapted to the needs and demands of different communities and different classes of people, and that in the beginning, at least until vocational education gets its "bearings, courses of study, textbooks, and some traditions worthy of preservation," special vocational schools will need to be established.

It is his belief that the whole question of vocational education is one for a state government to consider, that the state and the local communities should share in its expenses, and that the control of vocational education should be in the hands of existing state boards of education rather than under the direction of special commissions established for the purpose. The State needs also to give attention to the training of teachers for such work. Vocational education should be divided into three phases: (1) Intermediate, for children from 14 to 16 years of age, giving a training preparatory to entering occupations in the field of agricultural, trades, and manufacturing industries; (2) secondary, for pupils 16 or more years old, with a more or less direct connection with the intermediate vocational training and highly specialized courses for the development of skill and knowledge of direct practical value; and (3) advanced vocational or technical training which is already provided for in the system of land-grant colleges.

Agricultural education, W. H. French (Moderator-Topics, 31 (1911), No. 31, pp. 619, 620).—This article mentions the different phases of agricultural work that may be done in a high school and a few problems which have been solved by the young men in some of the Michigan schools.

The teaching of agriculture in the high school, G. A. Bricker (New York, 1911, pp. XXV+392, pls. 16, figs. 3).—The author considers in this book three critical problems of vocational education. The first of these concerns itself with the desirability of establishing separate schools for the teaching of agri-
culture; the second has to do with the possible outcome of any form of education that makes a strong appeal to economic motives; and the third, the possibility that, in the emphasis necessarily placed upon the economic factor, the broader "cultural" values of the study of science may be lost to view.

The book deals with the nature of secondary agriculture, the rise and development of secondary education in agriculture in the United States, and the social results of secondary agriculture, claiming that "the adolescent boy or girl should live in an elementary way the life that he expects to live more intensely later; and the more nearly the high school approaches this ideal condition, the better is the school." It is argued that secondary agriculture should be taught as a separate science. Other subjects discussed are the psychological determination of sequence, the seasonal determination of sequence, the organization of the course, aims and methods of presentation, and the organization of the laboratory and field work. An illustrative list of classified exercises is given, and a rough classification of recent textbooks on general agriculture is arranged in an appendix. Dr. W. C. Bagley states in the introduction that "if the essence of true culture is to see the fundamental and eternal shining out through the seemingly trivial and transitory, there is no subject better adapted to provide culture than the subject of agriculture."

General agricultural chemistry, E. B. HART and W. E. TOTTINGHAM (Madison, Wis., 1910, pp. 334, figs. 22).—The authors of this book give a survey of the general field of chemistry applied to agriculture. It treats of such subjects as the soil, crops and their essential food requirements, commercial fertilizers and their ingredients, the part played by the atmosphere and natural waters in making available plant food, a study of the animal body, feeding standards, food requirements of animals, and milk and its products. An appendix containing tables for reference is a feature of the book.

Laboratory exercises in farm management, G. F. WARREN and K. C. LIVERMORE (New York, 1910, pp. Xll+158).—This is a laboratory guide devoted almost entirely to exercises and problems in the various phases of farm management. They deal with the business of farming, the selection and purchase of the farm, its management under different systems, and such questions as marketing and keeping farm records. Twenty-two pages are devoted to references to the literature.

The accredited farm system, D. H. OTIS (Wis. Country Mag., 5 (1911), No. 4, pp. 129-132).—The author describes a system of instruction of an advanced nature in farm practice recently inaugurated by the college of agriculture of the University of Wisconsin on 12 accredited farms in Wisconsin, as previously noted (E. S. R., 24, p. 497), and gives details concerning the factors that are considered essential in the selection of accredited farms and the prerequisites for students seeking positions on these farms.

Judging and testing corn, D. W. WORKING (W. Va. School Agr., 1 (1911), No. 4-5, pp. 66-68, figs. 11).—Twelve lessons are outlined for schools on the method and purpose of judging and testing seed corn. Each lesson is accompanied by a laboratory exercise and one or more references to helpful literature.

Studies of aquatic insects, L. S. HAWKINS (Nature-Study Rev., 7 (1911), No. 4, pp. 91-96).—A suggestive outline for the study of aquatic insects in the grades is given for the fall and spring. It is suggested that this work may be correlated with art and English. The first lesson should be occupied with a study of the insects. Following this may be the drawing lessons, and then the study of the literature of the subject.

Lessons from the forest, E. R. JACKSON (Amer. Forestry, 17 (1911), No. 1, pp. 3-18, figs. 14).—The author discusses in a general way the place of forestry in public school education, and then takes up more specifically the relations of
forestry to nature study, elementary agriculture, botany, and geography in public school courses, showing in each case some interesting points of contact.

Outline lessons in housekeeping, including cooking, laundering, dairying, and nursing for use in Indian schools (U. S. Dept. Int., Off. Indian Aff. [Pub.] 1911, pp. 23, fig. 1).—This manual has been compiled from the results of practical experience in the work of instruction in the Indian schools. It contains a list of reference books and text-books, estimates for equipment, outline lessons for the first, second, and third terms in cooking, laundering, dairying, and nursing, and a tentative program of a week's work in a boarding school.

Synopsis of course in sewing (U. S. Dept. Int., Off. Indian Aff. [Pub.], 1911, pp. 38, figs 17).—This is an illustrated practical manual consisting of suggestions intended to assist teachers in giving instruction in sewing. It has been compiled from the results of practical experience in the work of instruction in Indian schools.

Domestic science], MINNIE L. JAMISON (Bul. N. C. State Norm. and Indus. Col., 1 (1910), No. 1, pp. 43, pls. 3).—An account is given of the home economics courses offered at the North Carolina State Normal and Industrial College, together with a large number of recipes and directions for preparing foods of various sorts, and a discussion of kitchen conveniences for use in warm weather.

Report of the women's institutes of Ontario, 1910. G. A. PUTNAM (Rpt. Women's Insts. Ontario, 1910, pt. 1, pp. 112).—This report contains (1) statistics showing that the Province of Ontario has 90 women's institute districts, that the institutes in 1909-10 had a total membership of 16,104, that 5,483 meetings were held with a total attendance of 140,388, that 8,171 papers were read or addresses delivered at the institutes, and that the total receipts of the institutes were $20,235, and the total expenditures, $12,685; (2) addresses and discussions delivered and reports submitted at the annual convention, held at the Ontario Agricultural College, December 8-9, 1909; (3) a selected list of papers and addresses; and (4) a list of officers of women's institutes.

Agricultural education: Boys' agricultural clubs, B. M. DAVIS (El. School Teacher, 11 (1911), No. 7, pp. 371–380).—In this article the author reviews the literature concerning the early phases of the boys' agricultural club movement, gives considerable information secured by correspondence with those actually directing agricultural club work, and discusses the value of such work in bringing about a redirection of education in the country.

School gardening for Nebraska boys' and girls' club, ANNA V. DAY (Neb. Dept. Pub. Instr. Bul. 1, 4. ser., 1911, pp. 12, figs. 5).—Suggestions are given in this pamphlet for the planning, planting, and cultivation of school gardens, together with specific instructions concerning the culture of some of the more common garden vegetables and flowers.

School gardens of the Hawaiian Islands, V. MACCAUGHHEY (South. Workman, 39 (1910), No. 7, pp. 377–382).—This is a brief account of the development, characteristics, purposes, and management of school gardens in Hawaii, including a list of books relating to school gardens.

School gardens in Jamaica, P. W. MURRAY (Bul. Dept. Agr. Jamaica, n. ser., 1 (1911), No. 4, pp. 280–285).—This lecture delivered at the agricultural course for school teachers in 1911 defines the functions of school gardens as to bring the child in touch with nature and enable him to appreciate it, to develop the power of observation and accuracy, to train directly for life's vocation, and to correct the tendency to avoid agricultural pursuits now evident in certain portions of the island. It also discusses school gardens in home life, school gardens as practical object lessons for classroom work, planning a garden, the practical use of school gardens, experimental work in school gardens, and their ornamental aspects.
School gardens in Ireland (Dept. Agr. and Tech. Instr. Ireland Jour., 11 (1910), No. 1, pp. 129-131, pls. 2).—This is a brief description of school garden work in Ireland, showing the methods adopted in putting to practical use the gardens attached to the country national schools.

These methods may assume one of the following three forms: (1) In which the teacher, having himself received some training in agricultural and horticultural practice, directs and supervises the laying out of the garden into plats for the cultivation by the pupils of the more common farm crops and kitchen vegetables; (2) in which the space is utilized solely for the cultivation of the vegetables more generally required in plain domestic cooking, the chief object aimed at being to make the pupils familiar with the use of the ordinary garden tools and to give them a practical knowledge of vegetable cultivation; (3) in which the school garden may be chosen as a suitable center for a horticultural demonstration plat, enabling students to follow, under the direction of the teacher, the best methods of growing vegetables and fruit.

An account is given of three typical school gardens representing the above classifications, viz. at the Tallow National School, County of Waterford, the St. Johnston National School, County of Donegal, and the Newmills National School, County of Tyrone.

NOTES.

Colorado College and Station.—The general assembly has made appropriations to the college aggregating $200,000, of which $90,000 is to be used for improvements and maintenance, including $10,000 for general station and extension work.

The assembly also accepted the Fort Lewis and the Grand Junction Indian schools from the Federal Government, and passed a bill reorganizing them as secondary schools of agriculture and mechanic arts under the direction of the State board of agriculture. An appropriation of $80,000 was made for the Fort Lewis school during the next biennium, and $10,000 for the Grand Junction school. The latter institution will not be in operation the next two years, except that the buildings will be used for short courses in agriculture and home economics. G. F. Snyder, formerly principal of the Sauk County Training School in Wisconsin, has been appointed principal of the Fort Lewis school, which it is planned to open next fall.

Hawaii College.—According to a note in Science, an appropriation of $75,000 was granted by the recent Territorial Legislature in addition to $20,000 for maintenance. Grounds comprising about 90 acres, of which 30 acres were set aside by the Government, are now available at Manoa.

Iowa College and Station.—The legislature renewed for another period of 5 years the mill tax for the erection of buildings. It is estimated that over $1,000,000 will be available for this purpose during the next 6 years. A library to cost $225,000 and a stock-judging pavilion to cost $20,000 were among the buildings definitely authorized.

Special appropriations were also made of $60,000 for equipment of the domestic technology building, gymnasium, and veterinary hospital, $6,000 for improvement of the grounds, $45,000 for the heating plant, $50,000 for general instruction, $15,000 for extension work, $15,000 for the station, and $5,000 each for the engineering experiment station, the roads work, and the 2-year-course.

C. V. Gregory, bulletin editor and head of the agricultural journalism department, has resigned to become editor of the Prairie Farmer of Chicago.

Cornell University.—The college of agriculture is holding its first summer school from July 6 to August 6. The special purpose is the training of teachers in agriculture, nature study, and home economics, and groups of courses in each of these subjects are being offered.

Texas Station.—Director H. H. Harrington has resigned, to take effect July 1. He becomes agricultural director of the St. Louis, Brownsville and Mexico Railroad, with headquarters at Kingsville, Texas.

Utah College and Station.—The legislature at its recent session provided a permanent appropriation for the maintenance of the college of slightly more than one-third of a mill, which it is estimated will amount to $150,000 during the ensuing biennium. The legislature also increased the number of trustees from nine to thirteen, and provided that the secretary of state should be a mem-

104
ber of the board. The following new appointments were made: J. A. Hyde, Nephi: Angus T. Wright, Ogden; J. M. Peterson, Richfield, and C. S. Tingey, secretary of state, Salt Lake City (ex officio).

A bill was passed allowing the college to offer degree courses in agricultural engineering, this to include courses in irrigation, drainage, public roads, water supplies and sanitation, farm buildings, and farm machinery.

Special laws were enacted granting permanent annual appropriations for the maintenance of the extension work and of the experiment station. These provide $20,000 for extension work and $30,000 for the experiment station during the biennium. A special appropriation of $50,000 was made for a gymnasium, to which Hon. Thomas Smart, of the board of trustees, added $10,000, and from other sources $5,000 more was contributed. Forty thousand dollars was also appropriated for a power and light plant. The lands and buildings of the Pangnitch Indian School, recently turned over to the State, were transferred to the experiment station, together with an appropriation of $2,500 for equipment. These appropriations, together with the mill tax, will give the institution a little more than $300,000 for the biennium.

With the increase in funds for extension work, Prof. J. C. Hogenson will devote his whole time to the extension department, being located in Salt Lake City: Prof. John T. Caine, III, will give the greater part of his time to extension work, and a domestic science teacher for extension work will be employed.

F. S. Harris, formerly assistant chemist of the station, and more recently assistant in soils at Cornell University, has been appointed agronomist of the college and station. Mr. Harris takes his doctor's degree at Cornell this year. Ernest Carrol, M. Sc., of the University of Illinois, was appointed assistant professor of animal husbandry and associate in the station work. Frank L. West takes his Ph. D. from the University of Chicago this year and returns to his position as professor of physics. He will take up work in meteorology and soil physics with the station. C. X. Jensen, an assistant in plant pathology at Cornell University, has been appointed professor of botany and plant pathology and plant pathologist of the station. Mr. Jensen has been granted leave until January 1, 1912, in order to complete his work at Cornell.

E. G. Peterson, professor of bacteriology at the Oregon Agricultural College, has been appointed professor of bacteriology in the college. Prof. Peterson will receive his Ph. D. from Cornell this year. Prof. E. G. Titus, on leave for postgraduate work in Harvard University, returned July 1. J. E. Greaves, associate chemist, has returned from postgraduate work in the University of California with the degree of Ph. D. Erastus Peterson, assistant in agronomy, resigned in April to enter commercial work. A. E. Bowman, of the graduating class, has been appointed to the position. L. M. Winsor, another graduate, has been appointed assistant in agronomy and irrigation, and has taken charge of the cooperative work with the settlers on the recently opened Uintah Reservation. Fred Froerer, another graduate, has been appointed assistant in dairying and will take charge of cooperative milk testing work in the State.

Vermont University.—Dr. Cyrus G. Pringle, curator of the herbarium for many years and an early plant breeder and botanical collector, died May 25 at the age of 73 years.

Dr. Pringle began his extensive collections in 1874, and in the years following covered especially the Rocky Mountain region in this country and the entire territory of Mexico, for which country he was for several years official collector and on the flora of which he became a recognized authority. He had been botanical collector for Harvard University since 1885, and for several years forestry and botanical collector for the American Museum of Natural
History. The Pringle Herbarium at the university, containing nearly 100,000 plants from all over the world, remains as a lasting monument to his life work.

Dr. Pringle will also be remembered as one of the early plant breeders of the country. Among his productions was a beardless wheat bearing his name, which is believed to have been the first variety of this type to become commercially successful. He also developed high grade varieties of oats, and gave considerable attention to the improvement of potatoes.

Wisconsin University and Station.—According to a note in Chicago Dairy Produce, A. C. Baer has been appointed to take charge of a new line of work dealing with problems of city milk supply and ice-cream making. Courses of instruction will be offered for the training of students for positions in the city milk trade and ice-cream manufacturing plants, and investigations of some of the unsolved problems will be inaugurated.

A course in agricultural advertising is being offered in the university in connection with the work in agricultural journalism. The course comprises lectures on methods of farm advertising and practice in the writing of advertisements of live stock, seeds, dairy products, etc.

The Pure-bred Sire League is being organized by the department of horse breeding, as a voluntary nonincorporated state and national organization for the improvement of farm live stock by the use of pure-bred registered sires.

According to a note in Science, J. C. Marquis, instructor in agricultural journalism and agricultural editor, has resigned to accept the editorship of Country Gentleman, and has been succeeded by John Y. Beaty, associate editor of Farm and Home and Orange Judd Farmer. A. J. Rogers, jr., has resigned as instructor in horticulture in the university and assistant horticulturist in the station to engage in fruit farming in Michigan.

Wyoming Board of Farm Commissioners.—Under a law recently enacted by the legislature a board of three farm commissioners is to be appointed by the governor to direct experiments in dry farming. This board may employ a director of experiments and must report December 1, 1912, and biannually thereafter. An appropriation of $5,000 per annum is provided for carrying out the act.

U. S. Commissioner of Education.—P. P. Claxton, professor of education at the University of Tennessee, has been appointed U. S. Commissioner of Education to succeed E. E. Brown, who has resigned to accept the presidency of New York University. Prof. Claxton will assume the duties of his new position at the close of the Summer School for the South late in July.

Additional Experimental Farms in Quebec.—Land has been acquired by the Canadian Government for two experimental farms in Quebec. One of these is at Cap Rouge, near the city of Quebec, with over 300 acres of land and substantial farm buildings. The second farm is at Ste. Anne de la Pocaterie in Kamouraska county and has an area of about 125 acres.

New Experiment Stations in Spain.—Recent numbers of El Progreso Agricola y Pecuario announce the establishment of an agricultural experiment station at Burgos and of zoological stations at Aranda de Duero, Felaniz (Baleares Province), and Valdepeñas.

Special Training Courses for Employees of the Philippine Bureau of Agriculture.—Because of the handicap under which the Philippine Bureau of Agriculture has labored in having to draw veterinarians from the United States, where rinderpest, surra, and foot-and-mouth diseases do not exist, it has been found necessary to establish special training courses for employees of the bureau, in cooperation with the College of Veterinary Science. These courses deal with the characteristics of Philippine animal diseases, including selected reading on subjects connected with tropical veterinary sanitary science, lectures, and discus-
sions, and observation trips to important centers of veterinary work. Instruction is also given in the specific duties of the various officials.

As the facilities improve, it is intended so to expand the course as to make it more closely resemble the postgraduate training courses of the army and navy medical schools and the laboratory training course of the United States Public Health and Marine-Hospital Service. Other more elementary work is under consideration, including the training of the Filipino assistants.

Agriculture at Syracuse University.—A bulletin has been issued by Syracuse University announcing (1) a four-year course in agriculture, leading to the B. S. degree, and entitling graduates to the special certificate authorizing them to conduct agricultural courses in high schools subsidized by the State: (2) agricultural instruction in the university summer school for 1911; and (3) short winter courses in dairy husbandry and agriculture, beginning January 4, 1911.

The college courses will be available in September, 1911, but according to the announcement the work to be provided at that time is considered merely a preliminary step toward the establishment of a regular agricultural course. In this preliminary work the present facilities of the university will be utilized in conducting courses leading to specialization in agriculture with the aim of preparation for practical farm management or for teaching agriculture in the high school or other schools.” The courses offered are in agricultural bacteriology, agricultural botany, animal breeding, animal nutrition, agricultural chemistry, agricultural economics, rural social conditions, agricultural engineering, rural architecture and landscape design, economic entomology, agricultural geology, and meteorology, with field laboratory work and practical studies in farm management.

Progress at the Saskatchewan Agricultural College.—The buildings of the college will not be fully completed this fall, but it is hoped that a few students may be accepted. Work on the central building has been in progress for over a year; the stock-judging building, the agricultural engineering building, and the power plant are practically completed, and a dormitory, a horse and cattle barn, and a sheep barn will be built this summer.

The judging pavilion, which will cost $42,000, is a fireproof brick and cement structure, having a judging ring 90 feet long by 25 feet wide, and seating about 500 people. There is also a slaughter room with a seating capacity of 125, with a cooling room on one side and immediately adjoining it a large refrigerating room. A room for smoking meats is also provided.

The agricultural engineering building is 125 feet long by 75 feet wide and will cost about $60,000. A complete course in farm engineering for the agricultural students is being outlined. Agricultural extension work is under way, and experimental work is being organized as a part of the college work.

A New College of Agriculture in the Cape of Good Hope.—A new college of agriculture, known as the Grootfontein College of Agriculture, has recently been opened at Middleburg, on a site until recently occupied by a military remount station. This location is especially adapted to the purpose of agricultural instruction and demonstrations because it is typical of a vast area and is suitable for practical and scientific instruction in the breeding and management of ostriches, cattle, horses, sheep, goats, and pigs, and in dry-land farming, irrigation, and dairying. A research branch of the Cape agricultural department is also to be established.

R. W. Thornton has been appointed principal of the college. Eventually there is to be accommodation for 150 students, but at present only 50 will be admitted. The course of study, which extends over 2 years and leads to a diploma, comprises instruction in agriculture and live stock, veterinary science,
dairying, poultry farming, chemistry, botany, entomology, mechanics, mensuration, surveying, irrigation, agricultural engineering, and bookkeeping, and all kinds of practical work on the farm and in the dairy and shops. For the present applicants will be admitted from the seventh grade, but after January 1, 1913, only students who hold the matriculation examination certificate of the Cape University, or its equivalent, will be admitted. Numerous scholarships are available, including one of $529 a year, tenable for 2 or 3 years. to be awarded annually for advanced and specialized study abroad.

Short courses will be conducted during vacation periods in such subjects as irrigation, butter and cheese making, etc., provided sufficient funds are available.

Normal School Agricultural Institute.—The Central State Normal School, Mt. Pleasant, Mich., announces a five-day institute on agricultural and rural topics. The heads of the departments of chemistry, bacteriology, soils, horticulture, and forestry of the Michigan Agricultural College and members of the agricultural and home economics faculty of the normal school will discuss their subjects in relation to the rural schools, and a representative of the state grange will discuss The New Rural Sociology. There will also be discussions of the new rural spirit and conferences on various subjects taught in the rural schools.

An Agricultural High School in a Normal School.—The Third District Normal School, at Cape Girardeau, Mo., in addition to its regular courses for teachers, is conducting an agricultural high school. The work includes (1) a four-year secondary course intended for farm boys who desire to enter an agricultural college, (2) a boys' short course, running 6 weeks in winter and conducted at Cape Girardeau, to farm mechanics and agricultural science, and (3) a school for farmers, lasting from 10 days to 2 weeks.

National Farm School.—Pennsylvania Hall, the new dormitory recently erected by the State of Pennsylvania, was dedicated June 4 by Governor John K. Tener. Between six and seven hundred visitors were in attendance. Among other addresses was one by Jacob A. Riis, of New York City, and one by ex-Senator Lafayette Young of Iowa.

Agriculture in a Trades School.—The trustees of the Williamson Free School of Mechanical Trades, which is located about 16 miles from Philadelphia in Delaware County, Pa., have decided to add agriculture to the list of 5 trades now taught in the school. The work of the institution is of elementary grade.

School Farms.—According to the Farm and Fireside of April 25, the superintendent of schools in Wake County, N. C., assisted by the Women’s Betterment Association of the county, has successfully inaugurated 11 school farms, each having an area of about 2 acres and planted to cotton, tobacco, corn, and wheat. These are conducted in connection with rural schools, and are worked by both children and adults, each work-day on the school farms being made a social event. Over 1,200 persons have participated in the work.

Agriculture in the Public Schools.—According to a recent issue of Deseret Farmer, the state board of education of Utah has provided that every accredited high school in the State must teach agriculture in order to participate in the maintenance fund provided for high schools.

A New Agricultural School in Yucatan, Mexico.—An agricultural school is soon to be established in the State of Yucatan by the department of promotion, acting conjointly with the governor of Yucatan. In connection with the agricultural school there will be a department for instruction in the various crafts. The entire institution will be known as the Lorenzo Ancona Castillo School, and will be in charge of a president to be selected annually. The ground for the building has been selected and the plans of some of the buildings prepared.
Actual building will be begun as soon as possible and it is planned to have the school in operation by next winter.

A New Avicultural School in Argentina.—The Consul General of Buenos Aires reports that a school of aviculture is to be established at La Plata as an annex to the zoological garden, to give instruction in poultry and bee keeping and in the rearing of rabbits and pigeons, the latter for consumption and as carriers. A course in carpentry and other trades necessary in the work of an aviculturist will also be offered.

A Vernacular Agricultural School in Bombay.—A vernacular agricultural school was opened as an experiment at Poona on June 10, 1910, in charge of K. M. Pawalir and an assistant. Twenty-one boys were admitted to the 2-year course, which is open preferably to boys between 13 and 16 years of age. A part of the agricultural college farm is to be used for practical work. The boys spending 16 out of 32 school hours a week in actual field work.

County Staffs of Instructors in Agricultural Subjects in England and Wales.—A report has recently been issued by the rural education conference, which was established by the presidents of the Board of Agriculture and Fisheries and the Board of Education in 1910, with reference "as to whether it is desirable that each county should have its own staff of instructors in agriculture, horticulture, and other allied subjects; or whether it is possible that the services of a single staff should be made available for groups of contiguous counties; as to the training and qualifications which such instructors should possess in order to enable them to secure the confidence of agriculturists; and as to the manner in which the staff should be composed for each county, or group of counties, in England and Wales, in view of the different branches of rural industries followed in each locality."

The conference reviews the status of the different counties in this respect and states that the great majority of the counties have a separate staff of their own, which is often supplemented and the work supervised by the staff of the center with which the county is associated; and that the only grouping of counties is for the purpose of establishing or assisting to maintain a joint college or institute, or more often arises out of association with such a center for agricultural education and research. In the case of certain counties no center at present exists with which they could conveniently be associated. The conference considers that every county either should be associated in combination with other counties with an efficient center, or if not in combination, should have a minimum efficient staff of its own; that it is desirable, especially in view of the difficulty of obtaining trained teachers, to concentrate higher agricultural education as far as possible in a few efficient centers; that any county council which is unable or unwilling to establish a minimum staff of its own, should associate itself with the council of an adjoining county; that the minimum staff should consist of an agricultural organizer or adviser, a horticultural instructor, and in most counties, a dairy instructor, to be supplemented by competent scientific investigators from the university or agricultural college, and instructors in special branches of agriculture. The report also defines the duties and qualifications of such a staff and gives specimens of existing staffs of typical counties.

Agricultural Education in Hungary.—Consul General Paul Nash, of Budapest, reports that agricultural subjects are taught in all Hungarian schools. There are 7 agricultural colleges with experiment stations for the maintenance of which the budget for 1911 provides $192,000. There are also 32 agricultural schools of lower grade for which the cost of maintenance in 1911 is estimated at $865,000. Of this Parliament has appropriated $702,000, the balance coming from tuition fees, etc.
Necrology.—Through the death of Dr. Saturnin Arloing, the noted French bacteriologist and director of the Veterinary School of Lyon, which took place March 21 at the age of 65 years, the veterinary profession has lost one of its leaders.

Dr. Arloing graduated from the Lyon Veterinary School in 1886 at the age of 20. Soon after he joined the staff of this school and remained until 1870, when he was called to the chair of anatomy at the Toulouse Veterinary School. He returned to Lyon in 1876 as professor of physiology and 10 years later was appointed director of the school, a position which he held until his death. In 1884 Dr. Arloing was also appointed professor of physiology to the Faculty of Sciences at Lyon and 2 years later to the chair of experimental and comparative medicine. In 1900 he founded the Pasteur Institute at Lyon.

Dr. Arloing conducted valuable studies in anatomy and physiology, particularly of the nervous system, the sterilizing action of sunlight on anthrax spores, the rôle of streptococci in puerperal septicemia, on toxins, antitoxins, etc., and was a collaborator in the preparation of recent editions of Chauveau’s Comparative Anatomy and the author of a valuable work on histology. His principal work was in the field of bacteriology; with his collaborators, Cornevin and Thomas, he was the first to demonstrate fully and describe the bacillus of symptomatic anthrax. The method of protective inoculations against the disease which these 3 workers devised has since been practiced successfully throughout the world. It was, however, to the investigation of tuberculosis that a large part of his time was devoted, during the last 10 years special attention being given to the antituberculous inoculation of cattle. In 1908 he visited this country and participated in the meetings of the International Congress of Tuberculosis, being one of the leading opponents of Koch’s theory of the nontransmissibility of the bovine type of the tubercle bacillus to man.

During his lifetime Dr. Arloing received many public and professional honors, such as the Commandership of the Legion of Honor, membership in the National Academy of Medicine, and honorary membership in the American Veterinary Medical Association.

Country Life Meeting in Vermont.—At a recent meeting at White River Junction, Vt., under the auspices of the Windsor County Y. M. C. A., addresses bearing on the country life problem were delivered by ex-President Theodore Roosevelt, President Kenyon L. Butterfield, of the Massachusetts Agricultural College, and Albert E. Roberts, international secretary of the Y. M. C. A. President Butterfield took for his subject The Cooperation of Community Institutions, pointing out that rural progress is to be attained through the cooperation of all forces interested in rural development.

Sixth Dry Farming Congress.—The 1911 session of this congress will be held at Colorado Springs, Colo., October 16-20.

Miscellaneous.—R. Newstead, lecturer in economic entomology in the Liverpool School of Tropical Medicine, has been appointed to the newly established professorship of entomology in the University of Liverpool.

The April Bulletin of the Pan American Union states that Fernando Bercelo has donated for a period of ten years 250 hectares of land in Bahia Blanca, Argentina, for the establishment of an industrial agricultural school.

A recent number of the Deutsche Landwirtschaftliche Presse announces the establishment of a chair of city and rural architecture at the Technical High School of Danzig.
EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, Ph. D., Assistant Director.
Assistant Editor: H. L. KNIGHT.

EDITORIAL DEPARTMENTS.

Agricultural Chemistry and Agrotechny—L. W. Fetzer, Ph. D., M. D.

CONTENTS OF VOL. XXV, NO. 3.

Recent work in agricultural science ................................................................. 201
Notes ......................................................................................................................... 300

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

The organic chemistry of nitrogen, Sidgwick ....................................................... 201
Studies in the chlorophyll group, V, Marchlewski and Barabass ... 201
The nitrogenous substances of a nonprotein nature in the sugar beet, Smolenski. 201
Note on the nitrogenous constituents of grape must, Lewis ................................ 201
The chemical ripening processes of fruits, Ritter ................................................. 202
Post-ripening of fruits, particularly as to tannin, Manaresi and Tonegutti ........ 202
Investigations in regard to the hellebore group, I, II, Keller ......................... 202
Is the action of rennet one of cleavage? Couvreur ............................................ 202
A contribution as to the oxidases and reductases of cow's milk, Kooper .......... 202
The chemistry of honey formation, Küstenmacher ............................................. 203
In regard to the determination of nitrogen by the Kjeldahl method, Andersen . 203
Estimation of total nitrogen by the formaldehyde titration method, De Jager .. 203
Bacteriological method for available organic nitrogen, McCandless and Atkinson 204
Separation of calcium from magnesiu, Murmann ................................................. 204
Precipitation of magnesiu as ammonium magnesium arsenate, Raffa ............. 204
Titrametric determination of sulphuric acid by barium chromate, Roemer .... 204
Chemical analysis of moor soils and its value, von Feilitzen ......................... 204
Determining water and citrate-soluble phosphoric acid, Pellet ................. 205
The determination of the free acid in superphosphates, Guthrie and Ramsay . 205
In regard to the analysis of Thomas slag powder, Woy ................................. 205
The present status in regard to the valuation of Thomas slag powders, Woy .... 205
The behavior of the hairs of certain cereals with hydrochloric acid, Rosenthaler... 205
A new flour tester, Treuml ................................................. 206
Estimating the shell content of cocoa, Goëke .................................. 206
About the resorcin test in honey, examination by Wiemann and Wichmann ... 206
Depression of freezing point by vinegars as a check on composition, Silverman... 206
Detection of inositol for the identification of wine vinegars, Fleury ............ 206
Estimation of sulphurous acid in wine, Mathieu ................................ 206
[Detecting sulphured malt], Reinke ....................................... 206
To determine fusel oil in distilled liquors, Bascott .......................... 207
The chemical and bacteriological methods for examining milk, Rühm ...... 207
The control of the milk supply and milk examination, Lührig and Kressner .... 207
Examination of milk, Ackermann ......................................... 207
Electrical conductivity of milk and detecting water and electrolytes, Binaghi... 207
Table for obtaining specific gravity of milk from milk-ammonia mixture, Kooper... 208
Testing for the calcium carbonate in sterilized milk and cream, Eichholz .... 208
Determination of fat in cheese by the hydrochloric acid method, Hölt .... 208
Determination of sucrose in beet-sugar products by Clerget's process, Ogilvie ... 208
Determination of cane sugar and raffinose, Saillard ........................ 209
The determination of raffinose, Pellet .................................. 209
In regard to the presence of raffinose in raw beet sugar, De Whalley ...... 209
A uniform method for dry substances in sugarhouse products, Stanék .... 209
Estimation of water in raw sugars by the immersion refractometer, Stanék ... 209
How sugar is tested, Baker .............................................. 209
Influence which inactive substances have upon the rotation of levulose, Wender ... 209
The reaction ratio of aldehyde and keton sugars to Fehling's solution, Remy ... 209
Staining of glycogens, Mayer ............................................ 209
The iodin reaction for starch, Harrison .................................... 210
An improved (Scherer) reaction for inosit, Salkowski ........................ 210
The biochemical detection of glucosids decomposable by emulsin, Bourquelot ... 210
Estimation of formic acid, Joseph ....................................... 210
Simple method for determining formaldehyde, Herrmann ........................ 210
A method for determing free and combined oxalic acid in plants, McAbee ... 210
Determination of free sulphur in condimental feeds and conditioners, MacNider ... 211
The clinical detection of glucose in the urine of domestic animals, Dolz .... 211
Estimation of nicotine in concentrated tobacco juices, Ulex ................ 211
Determination of nicotine in concentrated tobacco juices, Schröder ....... 211
The determination of nicotine in concentrated tobacco juices, Kissling .... 212
Karite and its products, Ammann .................................... 212
Malt vinegar and maize vinegar, Juritz ..................................... 212
Yeast cultures for the fermentation of fruit juices, Alwood .................. 212
The use of chicory for producing alcohol, Donfelt .......................... 212
Foreign varieties of tobacco conserves .................................. 212
Tomato-seed oil, Accomazzo .............................................. 212
Technology of impregnation, Kolker ..................................... 213

METEOROLOGY—WATER.

Climatic influences in the economic development of Australia, Van Cleef ... 213
Meteorological observations at Massachusetts Station, Ostrander and Damon .. 213
The disinfection of water, Perkins ....................................... 213
Nonrelation of the natural ice supply to typhoid fever and dysentery, Hill .... 213
The handling and utilization of sewage sludge, Eslner ........................ 213
Night soil—a valuable manure, Kelkar .................................... 213
[Experiments with night soil], Main ...................................... 214

SOILS—FERTILIZERS.

Method for determining lower limit of available soil moisture, Briggs and Shantz ... 214
Contributions to our knowledge of soil fertility, I, Greig-Smith ................ 214
On the importance of human bodies, Fischer .................................. 215
The new science of the soil, Beal ....................................... 215
The importance of soil maps to soil science and agriculture, Blanck ........ 215
Soils of New South Wales, III, Jensen .................................. 215
The German moors and their agricultural importance, Tacke .................. 216
Moor cultivation in Germany, Oliver .................................... 216
CONTENTS.

The acid content of moor water, Endell .................................................. 216
The improvement of marsh soils, Lueddecke. ......................................... 216
How can the farmer maintain the fertility of the soil? Hopkins .................. 216
The value of different crops as green manures, Hall .................................. 216
The fisheries and the guano industry of Peru, Coker ................................. 216
Bat and bird guanos in India, Burkill ...................................................... 216
Report of experiments with nitrogenous manures, Milburn and Gault .............. 216
The utilization of the nitrogen of the air, Frenzel .................................. 217
Preparation of nitric acid from the air by the Pauling process, Vanderpol .... 217
Use of cyanamid in France, Mason .......................................................... 217
Results of fertilizer experiments with potassium silicate during 1910, Wein .... 217
Investigations on the action of ground phonolite, Krüger et al .................... 217
Fifty years of the German potash industry, Krische ................................ 217
The fertilizing value of certain phosphatic materials, Grégoire and Hendrick .... 217
The production of phosphate rock in 1909, Van Horn ................................ 217
The gypsum industry in 1909, Burchard ................................................. 218
Rocks and waters of Roman Campagna as to lime, De Angelis d'Ossat ............ 218
Molasses as a fertilizer, Martin ............................................................... 218
On the composition and fertilizing value of peat ash, von Feilitzen .............. 218
[Fertilizing materials], Darbishire and Goodwin ....................................... 218
Analyses of fertilizers sold in Maryland, McDonnell et al ........................ 218
Inspection of commercial fertilizers, Trowbridge et al ................................ 218
Analyses of fertilizers, Kilgore et al ...................................................... 218
Commercial fertilizers, Fulmer ............................................................... 219

AGRICULTURAL BOTANY.

The water balance of succulent plants, MacDougall and Spalding .................. 219
Estimating gaseous exchanges of submerged plants, Blackman and Smith ........ 220
On assimilation in submerged water plants, Blackman and Smith ................. 220
Relation of living cells to transpiration and sap flow in Cyperus, II, Overton 220
Temperature coefficient of the duration of life of barley grains, Goodspeed .... 221
Chlorophyll and light in transformation of CO₂ and aqueous vapor, Dubose .... 221
Respiratory energy of plants cultivated in different degrees of light, Rosé .... 221
The portion of the spectrum influencing photosynthesis, Dangeard ............... 221
Leaf decay and autumn tints, Keegan ...................................................... 221
The influence of acidity on germination, Promsy ....................................... 222
Use of solutions of potash to determine germinative faculty of seeds, Lesage .. 222
Effect of activation of atmosphere by radium on germination and growth, Fabre 222
Nitrogen and chlorophyll in galls and etiolated leaves, Molliard .................. 222
The utilization of ammonium salts by green plants, Pantanelli and Severin .... 222
Investigation of the utilization of green leaves, Otto and Koenig .................. 223
Absorption of barium, strontium, and calcium, Colin and De Ruiz de Lavison ... 224
Excretion of mineral and organic substances by roots and water pores, Mazé . 224
Reduction by roots, Schreiner and Sullivan ............................................. 224
Some investigations on the action of wind on plant growth, Cavara .......... 224
Plants and tobacco smoke, Molisch ....................................................... 225
The comparative toxicity of vegetable volatile oils on plants, Coupin .......... 225
The use of saponin in the preparation of insecticides and fungicides, Gastine 225
Agricultural bacteriology, Percival ....................................................... 225
A bacteriological museum at the American Museum of Natural History, Winslow 225
The proposed microbiological central station in Berlin, Rahn ...................... 225
Contributions to the cytology of the bacteria, Dobell ............................... 226
Nuclei equivalents and nuclei of Azotobacter chroococcum, Mencl .................. 226
On the mineral needs of Azotobacter, Kaserer ....................................... 226
Viability of Pseudomonas radicicola on ash-maltose-agar, Edwards ............... 226
The influence of quartz sand upon microbial cultures, Rahn ........................ 226
Biochemical factors in the soil, Sullivan ............................................... 226
Bacteria of frozen soil, Conn ............................................................... 227
On methods of measuring the bacterial activity of cultivated soils, Perotti ... 227
Ammonification in soils and in solutions, Stevens, Withers, et al ................. 227
Determining nitrifying and ammonifying powers of soils, Stevens and Withers 227
Bacteriological studies of soils of Truckee- Carson project, Kellerman and Allen 227
Upon assimilation of atmospheric nitrogen by fungi, Pennington .................. 228
Experiments with cyanamid-decomposing bacteria, Kappen ........................ 228
The clogging of drain tile by roots, Stone ............................................. 228
The mycophism theory and metachromatic corpuscles, Beauverie............ 229
Variation of fungi due to environment, Stevens and Hall.................. 230
A quantitative study of variation in pure lines of Silene noctiflora, Humbert. 231
On inheritance of mutation in the common foxglove, Saunders.............. 232
Seeds and plants imported from Jan. 1 to Mar. 31, 1910.—Inventory No. 22.. 232
Seeds and plants imported from Apr. 1 to June 30, 1910.—Inventory No. 23.. 232

FIELD CROPS.

Experimental work [with field crops]........................................... 230
Summary of five years' results of cooperative tests, Wiancko and Croner.... 230
Report on the Partabgarh Agricultural Station for 1910, Hadi................. 231
Progress of grain investigations, Willis and Champlain...................... 231
Lucern, O'Grady........................................................................... 232
The history of the clover-seed traffic in Vermont, Carpenter............... 232
Characters of the corn plant associated with yield, Williams and Etheridge. 232
Corn production, Calvin.................................................................. 232
Cotton, De Wildeman et al.............................................................. 233
Report on the present position of cotton cultivation, Dunstan................ 233
Cotton production, Calvin................................................................ 233
Effect of different fertilizing materials on the maturity of cotton, Williams. 233
Cultivation of broach cotton in Dharwar, Kulkarni............................... 234
Hindi cotton in Egypt, Cook.............................................................. 234
Proceedings of the cotton culture commission of the colonial committee. 234
Cotton growing in Ceylon................................................................ 234
Fibers used in textile and allied industries, Mitchell and Prideaux.......... 234
Studies on microscopical examination of fibers for technical purposes, Korn. 235
Report of field trials with varieties of oats, Milburn and Patten............. 235
Experiments by the German Potato Culture Station in 1910, von Eckenbrecher. 235
Experiments with potatoes in 1910 at Kloster, Hadmersleben Oetken........ 235
Varieties of potatoes utilized for manufacturing starch, Parow.............. 235
Analyses of potatoes grown in 1909 and 1910, Hoffman........................ 235
Some potato fertilizer tests, Hall...................................................... 235
Literature on the races of rice in India............................................. 235
Chemical structure and its influence on sugar content of Beta vulgaris, Claassen. 236
The influence of light on the composition of the sugar beet, Strohmer et al. 236
An experiment on manuring swedes, 1907 and 1908, Porter and Gau........... 236
Tobacco culture in Wisconsin, Johnson............................................. 237
Conference of wheat growers, with special reference to dry farming, Perry. 237
Adulteration and misbranding of seeds, Taylor.................................... 237
Orange hawkweed or paint brush, White........................................... 237

HORTICULTURE.

Fertilizer experiments with small fruits, vegetables, and flowers, Heine.......... 237

American gooseberry mildew, Middleton ................................................................................... 247
The American gooseberry mildew, Salamon ............................................................................. 248
The Sclerotinia (Botrytis) disease of the gooseberry, or die-back, Salmon ............................... 248
Teratological forms of Oxycoccus macracarpus, Shear ................................................................. 248
On the abnormal branching of Asparagus sprengeri, Grevilleus ............................................. 248
Carnation alternarieose, Stevens and Hall ................................................................................... 248
The mildew of the oak, Mangin ................................................................................................... 248

ECONOMIC ZOOLOGY—ENTOMOLOGY.

A systematic synopsis of the muskrats, Hollister ..................................................................... 248
A study of the food of moles in Illinois, West .............................................................................. 249
A plague like disease of rodents, McCoy .................................................................................... 249
A contribution to the study of rat leprosy, Currie and Hollmann ............................................. 249
Report of the State entomologist, Symons .................................................................................. 250
The insects of New Jersey, Smith ................................................................................................. 250
Report of entomologist, Smith ..................................................................................................... 250
Insect pests [in the West Indies, 1909-10], Ballou ..................................................................... 250
VI

CONTENTS.

Page.

Report of economic zoology for the year ending Apr. 1, 1909, Theobald.................. 250
Destructive insects and pests order, 1910.......................................................... 250
The principal insects injurious to horticulture during 1908-9, Swenk........................ 250
Report of the government entomologist for the year 1909-10, Gowdey...................... 251
Report of the entomologist [of Ceylon], Green.................................................... 251
Some insect pests of the sugar cane, Quelch....................................................... 251
Insects injurious to the peach trees in New Jersey, Smith.................................... 251
Insects injurious to citrus fruits and methods for combating them, Tower................ 253
Notes on some coconut pests, Guppy......................................................................... 254
Insects injurious to shade trees, Smith...................................................................... 254
Insects of the greenhouse and their extermination, Davis......................................... 254
The mole cricket (Scapteriscus didactylus), Fredholm........................................... 255
The Thysanoptera that attack Gramineae in Russia, Korolkova.............................. 255
Investigations of Philonthus oleae, Topi................................................................... 255
The apple red bugs, Crosby and Wilson.................................................................... 255
Harlequin cabbage bug (Mamantia histrionica), Smith........................................... 256
On the leaf-hoppers that injure the sugar beet in Bohemia, Uzel............................... 257
Description of a new coccid species, Ceroputo ambigua, with notes, Fullaway........ 257
Hematomus urius in transmission of infectious diseases of the pig, Bernazky........... 257
Notes on Chrysopa dorsalis, Alderson...................................................................... 257
Gipsy and brown-tail moth suppression, Rane......................................................... 257
Spraying for codling moth in Galloway orchard....................................................... 258
Spraying for the codling moth.................................................................................. 258

**Note.**—The price of *Experiment Station Record* is $1 per volume, and two volumes are issued annually. It may be purchased from the Superintendent of Documents, Washington, D. C., to whom all remittances should be made. The publications of the State experiment stations are distributed from the stations and not from the Department.
The organic chemistry of nitrogen, N. V. Sidgwick (Oxford, 1910, pp. X+415).—This book had its origin in lectures given to the more advanced students at the University of Oxford, and while in no sense directly intended as a work of reference it gives an account of the present state of knowledge in those parts of this subject which are of great theoretical interest and may eventually have a practical bearing.

The chapters of the book are as follows: Compounds with no nitrogen directly attached to carbon—esters of nitrous and nitric acids; bodies containing one nitrogen atom attached to carbon—amines, aromatic amines, anilides, derivatives of hydroxylamine, nitroso compounds, nitro compounds, carbonic acid derivatives, and cyanoamin derivatives; compounds containing an open chain of two or more nitrogen atoms—hydrazine derivatives, diazo compounds, azo compounds, azoxy compounds, nitramines, and derivatives of carbonic acid; compounds containing a chain of three or more nitrogen atoms—uric acid derivatives; and ring compounds.

Studies in the chlorophyll group.—V. Final proof of the identity of chlorophyllpyrrole and hemopyrrole, L. Marchlewski and L. Barabass (Biochem. Ztschr., 21 (1909), No. 6, pp. 548-550; abs. in Chem. Zentralbl., 1909, II, p. 2171; Chem. Abs., 5 (1911), No. 5, p. 871).—This work shows that hemopyrrole on condensation with benzamedazinium chloride yields two azo dyes, which have the formulas C₅H₅N₂C₅H₅N₅C₅H₅HCl and C₅H₅N₂C₅H₅N₅C₅H₅NN₅C₅H₅HCl. Both of these are also yielded by chlorophyllpyrrole.

In regard to the nitrogenous substances of a nonprotein nature in the sugar beet, K. Smolenski (Ztschr. Ver. Deut. Zuckerindust., 1910, No. 659, II, pp. 1215-1261).—The diffusion juices of a Russian sugar refinery were examined and found to contain the following nitrogenous but nonprotein bodies: Vernin, allantoin, asparagin, glutamin (>), and betain. No cholin nor tyrosin were present. Contrary to the statements which frequently appear, the author found that asparagin in an aqueous solution can increase the polarization, particularly when an excess of lead subacetate is employed. In concentrated alcoholic solutions, however, no increase in polarization could be noted. He points out that much more research will have to be done in order to establish whether asparagin or asparaginic acid is present in the beet itself, and also in regard to the optical properties of asparagin and asparaginic and glutaminic acids.

Note on the nitrogenous constituents of grape must, J. Lewis (Agr. Jour. Cape Good Hope, 37 (1910), No. 4, pp. 445-447).—The ammoniacal and
protein nitrogen contents of a number of varieties of grapes were determined. Both showed considerable variation during the growth of the fruit, especially when the fruit was immature and gradually becoming less when the fruit grew ripe. The amount of ammoniacal nitrogen, however, was subject to great variations, depending upon the place where the grape was grown and the variety of the fruit.

In regard to the chemical ripening processes of fruits, with particular reference to edible fruits, G. Ritter (Deut. Obstbau Ztg., 1910, No. 31, pp. 429–435).—A discussion in regard to the chemical processes involved, including general considerations in regard to the assimilation and respiration of fruits, the influence of air on the chemical ripening process, and the changes wrought as to water, proteins, carbohydrates, crude fiber, gums and pectin, fat and oily constituents, alkaloids, and acids during the ripening process, and with both early and late gathered fruits. The fruits considered are pears, blackberries, apples, cherries, plums, strawberries, raspberries, and currents.

Post-ripening of fruits, with particular regard to tannin, A. Manaresi and M. Tognoniti (Staz. Sper. Agr. Ital., 43 (1910), No. 5, pp. 369–395).—The fruits examined in this work were the meallor (Mesusulus germanicus), Italian service berry (Pyrus domestica), and Japanese persimmon (Diospyros kaki). The constituents determined were water, cellulosic sugar (invert), starch, ether extract, total nitrogen, protein nitrogen, ammoniacal nitrogen, total acidity, malic acid, acetic acid, alcohol, and tannic acid.

The results show that fruits which are mushy, or partially mushy, contain less tannin, malic acid, and sugar than properly matured fruits. Mature fruits contain less acetic acid and less alcohol. The other constituents were very variable.

Investigations in regard to the hellebore group, II. O. Keller (Arch. Pharm., 248 (1910), No. 6, pp. 463–467, 468–475; abs. in Ztschr. Gesam. Physiol. u. Path. Stoffwechsel, u. ser., 6 (1911), No. 2, pp. 63, 64).—Helleborus, Aquilegia, Caltha, and Delphinium were examined for alkaloids.

It was found that no alkaloids are present in the roots of Helleborus niger, and probably not in H. viridis. In the roots of the former over 0.045 per cent of helleborin was found. Aquilegia vulgaris did not contain alkaloids in the blossoms nor in the foliage or seeds, while in the foliage of Caltha palustris small amounts of alkaloids were present. The chlorids and double salt of platinum of the alkaloids are crystalline. The alkaloid is not identical with nicotin.

In the seeds of Delphinium consolida the author found alkaloids, but not in the blossoms. The foliage was not examined. A description of the nature and properties of the alkaloids in the seeds is given in the second paper.

Is the action of rennet one of cleavage? E. Couvreur (Compt. Rend. Soc. Biol. [Paris], 69 (1910), No. 37, pp. 579, 580).—Whey from milk which had been rapidly curdled and immediately treated with boric acid, filtered, and boiled with magnesium sulphate, did not show that rennet produces a cleavage of proteins. The xantho-proteic reaction present is probably an epiphenomenon.

A contribution to the knowledge of the oxidases and reductases of cow's milk, W. D. Kooper (Ztschr. Untersuch. Nahr. u. Genussmittel., 20 (1910), No. 9, pp. 564–575).—It appears from this work that the catalase in whole milk can be separated with the cream and by either the centrifugal or the ordinary cooling method. When the milk becomes older a catalase content increases until the acidity of the milk reaches 40° to 50° (each degree corresponding to 1 cc. of tenth-normal alkali for every 100 cc. of milk), when it begins to decrease again. The catalytic power can be conferred on sterile whole milk if a little catalytic raw milk is added, and is capable of multiplying itself. According to the
author, the catalase is probably of bacterial origin. It may be completely destroyed or weakened by the addition of various preservatives.

For reductase it was noted that the greater portion goes over into the cream when centrifugally separated, but that when separated by hand very much less passes over into the cream. Reductase multiplies more rapidly in skim milk than in whole milk, and according to this, this substrate in all probability is the best one to use when searching for reductase. The intensity of its action begins to rise until the acidity reaches 35° to 40°, then begins to fall, and later on begins to rise again. Its behavior toward antiseptics is the same as that of catalase. As the reductase increases to quite an extent when raw milk is added to boiled, the author concludes that it also is of bacterial origin.

Oxidase goes over into the skim milk irrespective of whether the creaming is done by the centrifuge or by hand, and when the milk becomes older no increase is noted. When the acidity degree rises to from 40 to 50 the blue color obtained with paraphenylenediamin begins to grow paler and diminishes until no reaction is obtained. This enzyme (?) is not destroyed by a dose of corrosive sublimate which is lethal for fermentation organisms, and contrary to the findings with catalase and reductase indirect oxidase does not multiply when raw milk is added to boiled milk. According to this, the enzyme is not of bacterial origin.

The author finally states that, although the test may be of value for food chemists and veterinarians, he doubts whether it will ever find a general introduction in the practical dairy industry.

The chemistry of honey formation, M. Küstenmacher (Biochem. Ztschr., 30 (1910), No. 3–4, pp. 237–254, pl. 1, fig. 1).—After discussing the anatomy and physiology of the honeybee, the author details the chemistry involved in the transformation of nectar into honey.

In regard to the determination of nitrogen by the Kjeldahl method, A. C. Andersen (Skand. Arch. Physiol., 25 (1911), No. 1–3, pp. 96–104).—When determining nitrogen in platinic sal ammoniac with the Kjeldahl method the author observed that a great loss of nitrogen takes place. Some further experiments made with milk, blood serum, and fresh egg albumin showed that when using platinum as a catalyst fairly good results could be obtained, while with urine, milk treated with pepsin or trypsin, old egg white, and hydrolyzed casein a large loss took place.

The author therefore does not recommend the use of platinic chlorid as a catalyst in the method. He also points out that the formal titration method does not offer any advantages in point of time or exactness over the usual Kjeldahl distillation and titration method.

Estimation of total nitrogen by means of the formaldehyde titration method, L. de Jager (Ztschr. Physiol. Chem., 67 (1910), No. 1, pp. 1–7; abs. in Analyst, 35 (1910), No. 4, pp. 487, 488).—The substance is digested with sulphuric acid, as in the Kjeldahl process, and the ammonia formed is titrated in the presence of formaldehyde. The method as applied to urine is as follows:

“Phosphates are first removed by treating 40 cc. of the urine with 5 gm. of sodium acetate and an excess of 10 per cent ferric chlorid solution. The mixture is diluted to a volume of 50 cc., weighed, boiled, water added to correct for loss by evaporation, and the precipitate is removed by filtration. Ten cc. of the filtrate are now digested with 8 cc. of sulphuric acid and 0.5 gm. of copper sulphate, and the copper is subsequently removed as sulphid by the addition of 10 cc. of 10 per cent sodium sulphid solution, the excess of hydrogen sulphid being boiled off. The copper sulphid is collected on a filter, washed, and the filtrate is diluted to a volume of 100 cc. Fifty cc. of this solution (corresponding to 4 cc. of urine) are now neutralized with sodium hydroxid solution, using phenolphtha-
lem as indicator, 6 ce. of neutralized formaldehyde solution are added, and the solution is titrated with tenth-normal sodium hydroxid solution."

A bacteriological method for determining available organic nitrogen, J. M. McCandless and F. C. Atkinson (Amer. Fert., 31 (1911), No. 7, pp. 17, 18; Journ. Indus. and Engin. Chem., 3 (1911), No. 3, pp. 174, 175).—The author describes a method similar to that proposed by Lipman (E. S. R., 23, p. 302), in which aqueous extracts of cottonseed meal and other organic nutrientous fertilizers were shaken up with soil and incubated for 210 hours at from 35° to 40° C., and the rate of ammonia formation under these conditions determined.

Separation of calcium from magnesium, E. Murmann (Ztschr. Analys. Chem., 49 (1910), No. 11, pp. 688–693; abs. in Ztschr. Angew. Chem., 23 (1910), No. 37, p. 2229).—According to the author an absolute separation of calcium from magnesium is possible only when enough sulphuric acid is present with 90 per cent alcohol to combine with or fix the calcium.

For conducting the separation the author adds a sufficient amount of titrated sulphuric acid to the solution of the chlorids and nitrates of calcium and magnesium to fix all the calcium, and after evaporating off the sulphuric acid aims to leave very little of the magnesium present as a sulphate. The residue is treated with 90 per cent alcohol, and the residual calcium sulphate filtered off, washed with the same strength alcohol, and treated in both an alkaline and acid solution to separate it from the magnesium which came down in the original precipitation as sulphate.

Precipitation of magnesium as ammonium magnesium arsenate, E. Raffa (Gaz. Chim. Ital., 39 (1900), I, No. 2, pp. 154–162; abs. in Chem. Abs., 5 (1911), No. 5, p. 844).—As the solubility of ammonium magnesium arsenate is about 0.037 part per 100 parts of water at 20° C., and 0.00303 to 0.00280 part per 100 in a mixture used for washing the precipitate and consisting of 1 part 10 per cent ammonia (NH₃) and 2 parts of water, the author proposes the use of the same procedure as described in previous work (E. S. R., 20, p. 1006). The precipitate is somewhat more soluble than the phosphate.

Titrametric determination of combined sulphuric acid by the barium chromate method, H. Roemer (Ztschr. Analys. Chem., 49 (1910), No. 8, pp. 490–492).—The method is a modification of the Holliger method (E. S. R., 23, p. 214) and is as follows:

To the salt, which is dissolved in hot water containing some hydrochloric acid, add the requisite amount of one-half-normal barium chloride solution, boil, titrate with an equivalent amount of standard solution of potassium bichromate (36.9 gm. per liter), add ammonium hydrate until the barium chromate separates, boil again, and filter off the barium sulphate and barium chromate. As the filtrate now contains an amount of chromate equivalent to the amount of sulphate originally present, it is titrated after acidifying with a few drops of sulphuric acid with ferric ammonium sulphate, using potassium ferricyanid as an indicator. This method is good where amounts as low as 0.1 per cent of sulphuric acid (SO₄) are present.

In regard to the chemical analysis of moor soils and its value for cultural purposes, H. von Felitzen (Verhandl. Internat. Agrarcol. Konf. [Stockholm], 2 (1910), pp. 160–167).—After reviewing the existing work on this subject, the author points out the advantage of utilizing for moor soils the extraction method which employs first a 4 per cent and then a 2 per cent hydrochloric acid solution for the purpose. A description of the method as used at the station of the Swedish Moor Culture Society is given, with a description of the method for interpreting the analytical results. For ordinary purposes quantitative analyses are made of the organic matter, the residue after calcination, and the calcium and nitrogen content, together with qualitative tests.
for substances injurious to plants, and the volume weight of the peat. At the same time a botanical, geological, macroscopical, and microscopical examination of the peat is made.

The determination of water and citrate-soluble phosphoric acid in superphosphates, H. Pellet (Ann. Pharm. [Rauenitz], 16 (1910), pp. 196–203; abs. in Bul. Sci. Pharmacol., 18 (1911), No. 3, pp. 186, 187).—In estimating the citrate-soluble phosphoric acid the author believes it advisable to treat the phosphate with ammonium citrate upon a boiling water bath. The results are a little higher than those obtained with other methods.

Note on the determination of the free acid in superphosphates, F. B. Guthrie and A. A. Ramsay (Jour. and Proc. Roy. Soc. N. S. Wales, 43 (1909), No. 1, pp. 69–71).—During the course of experiments to determine the cause of the reduction of the germinating power of wheat when brought into contact with superphosphate before sowing, the authors made a comparative test of the various methods in vogue for the determination of free phosphoric acid in superphosphates. Those examined were the Glicksman, Thomson, Gerhardt (E. S. R., 17, p. 111), Herzfelder (E. S. R., 15, p. 325), and the direct titration with sodium hydrate and utilizing various indicators.

From their work the authors conclude that none of these methods is satisfactory, and that although the Herzfelder method, which is based on the extraction of the phosphoric acid with ether and bringing it into an aqueous solution, utilizing methyl orange as the indicator, is the best, it yields only approximate results with phosphoric acid and is not neutral toward acid phosphate. They propose tentatively that a modification of the Herzfelder method be made to determine the free phosphoric acid in superphosphates, and that ether be used as the solvent for the free phosphoric acid, converting the ethereal solution into an aqueous one and titrating the free acid with a standard alkali solution, using sodium alizarin sulphonate as the indicator.

In regard to the analysis of Thomas slag powder, R. Woy (Ztschr. Öffentl. Chem., 17 (1911), No. 5, pp. 86–88).—The author discusses the advisability of eliminating some of the incongruous features of the Wagner method and simply determining all the citrate-soluble phosphorus that can be dissolved out of a given sample which has a definite degree of fineness without regard to temperature of solvent, number of times to be shaken or rotated, or length of time of exposure to solvent. He also points out the necessity of determining anew the strength of the solvent to be employed, and, furthermore, that the new method be made to serve also the purpose of detecting the presence of adulterants in slag powders. The possible value of the Dubbers method is also pointed out.

The present status in regard to the valuation of Thomas slag powders, R. Woy (Ztschr. Öffentl. Chem., 16 (1910), No. 23, pp. 452–463; Chem. Ztg., 34 (1910), No. 118, pp. 1047, 1048).—This is a critical discussion in regard to the methods in use for the valuation of Thomas slag powders, with some data in reference to the estimation of the citrate-soluble phosphoric acid according to the various citrate methods, when utilized under varying conditions and with particular reference to the silicic acid contained in the slag.

The behavior of the hairs of certain cereals with hydrochloric acid, L. Rosenthaler (Ber. Deut. Pharm. Gesell., 20 (1910), No. 7, pp. 368–371, fig. 1; abs. in Chem. Ztg., 34 (1910), No. 145, Repert., p. 598).—If the hairs at the tip of wheat are treated with concentrated hydrochloric acid (specific gravity 1.19) ribbon and spiral like forms spread from the hairs, or the hairs themselves curl up. This behavior could not be noted with the hairs from barley or rye, and therefore affords a means of distinguishing between these grains.

About the resorcin test in honey examinations, M. Nyman and A. Wichtmann (Pharm. Centralblatt, 51 (1910), No. 36, pp. 815-819).—The resorcin-hydrochloric acid reaction is considered a good test for detecting the adulteration of honey with invert sugar.

In regard to the methods for examining marmalades and their composition, F. Häretel and J. Sölling (Ztschr. Untersuch. Nahr. u. Genussmtrl., 21 (1911), No. 3, pp. 168-196, figs. 2).—While the authors agree with Beythen and Simmich (E. S. R., 24, p. 308) in regard to the theoretical conclusions, they do not coincide with them in regard to the practical execution of the analytical methods. They therefore give the methods which they have found by many years of trial to be very efficient. The work considers the methods for estimating the insoluble and soluble portions of the marmalade, the sugar, sugar-free extract, starch sirup, total acidity, ash and ash alkalinity, and jellifying substances, and the microscopic examination.

The results of analyses for glucose, sucrose and starch sirup, commercial sugar and crude raspberry juice, commercial sugars, starch sirup and raspberry juice, plum marmalade with starch sirup, apple marmalades, and nearly 150 samples of commercial marmalades and fruit preparations are also given.

Depression of the freezing point by vinegars as a check on their composition, A. Silverman (Jour. Indus. and Engin. Chem., 3 (1911), No. 3, pp. 173, 174, fig. 1).—"In every case where the depression of the freezing point remained within the limits cited in the tables, the vinegar was found to analyze up to the required standard."

Estimation of sulphurous acid in wine, L. Mathieu (Ann. Falsif., 3 (1910), No. 24, pp. 410-417).—The methods usually employed for determining free and combined sulphurous acid in wine are the Haas, Ripper, and Wartha. The Ripper method was found to give the highest results for both free and combined sulphurous acid, and in many instances this is more than the true amount of the acid present. This invalidates the method for samples which contain minimum amounts of free acid, but it can, however, be applied for total acid.

With the Haas method exact results can be obtained for both total and free acid, but only where the procedure for free acid is modified by oxidizing the sulphurous acid in the cold with iodin and titrating the excess of iodin with sodium arsenite. With the Wartha method danger exists from losses during condensation of the distilled water and also loss of iodin.

[Detecting sulphured malt], O. Reinke (Chem. Ztg., 34 (1910), No. 130, p. 1139, fig. 1; abs. in Jour. Soc. Chem. Indus., 29 (1910), No. 22, p. 1324).—An aqueous extract of the malt is distilled with phosphoric acid in a current of carbon dioxid. The resulting sulphurous acid is absorbed in a solution of iodin, and the sulphuric acid produced is precipitated with barium chlorid. With this procedure it often happens that no precipitate is produced with barium chlorid,
but when tested qualitatively with zinc and sulphuric acid, a dark brown stain is obtained upon lead acetate paper. This coloration is due to organic bodies.

To determine fusel oil in distilled liquors, H. P. Bassett (Jour. Indus. and Engin. Chem., 2 (1910), No. 9, pp. 389, 390).—This method is a modification of the Savelle method, and is as follows:

"To 25 cc. sample add 5 cc. of a normal alkali solution and digest for 1 hour on the water bath under a reflux condenser to saponify the esters, then connect with a suitable distilling apparatus and distill 25 cc.; add 5 cc. of water and distill an additional 5 cc. To this distillate add 0.2 gm. of m-phenylene diamine hydrochlorid and boil under a reflux condenser for 1 hour to remove the aldehydes, after which distill, collecting 25 cc.; add 5 cc. of water and distill an additional 5 cc., bringing the distillate up to the original volume. To this distillate add slowly an equal volume of [pure] H₂SO, concentrated, heat nearly to boiling, and while still hot add 5 to 10 drops of a 1:1000 solution of furfural; a pink or red color will develop in the presence of the higher alcohols, which may be compared with a standard solution of amyl alcohol treated in the same manner. By this method less than 0.01 per cent of fusel oil can be determined and 1 part in 20,000 detected."

The chemical and bacteriological methods for examining milk, G. Rüm (Ztschr. Fleisch u. Milchhyg., 21 (1910), Nos. 1, pp. 14–19; 2, pp. 47–51; 3, pp. 78–83).—This is a description and critical discussion of the various bacteriological and chemical methods for examining milk. Their value to the veterinary profession is particularly considered.

The control of the milk supply and milk examination, H. Lührig and L. Kressner (Molk. Ztg. [Hildesheim], 25 (1911), No. 4, pp. 37–50).—The authors point out that the value of the calcium chlorid serum test (E. S. R., 23, p. 309) is greatly dependent upon the system of milk control which is in vogue in the community where it is to be applied. They first discuss the various factors which influence the fat, etc., content of milk, and then give their results of a study made in regard to such influencing factors.

They report that sodium bicarbonate, borax, boracic acid, and sodium chromate, in concentrations ranging from 0.005 to 0.1 per cent in aqueous solutions, have no influence on the refraction. Formalin has an influence, as when over 0.3 cc. were present a slight increase in refraction could be noted, but not in the amounts in which it is employed as a milk preservative. Sodium bicarbonate did not even show an effect when 0.1 per cent was added. On the other hand, boracic acid, borax, and sodium chromate began to show their influence with concentrations ranging from 0.08 to 0.1 per cent. Salicylic acid when present shows itself as an additional refraction, and with as small an amount as 0.05 per cent in an aqueous or milk solution. It is used in this quantity as a preservative.

As a result of examining normal milks the authors found the greatest deviation in the morning milks to be 1.3 scale divisions, in afternoon milks 1.05 divisions, and in evening milks 1.5 scale divisions.

Examination of milk, E. Ackermann (Abs. in Chem. Ztg., 34 (1910), No. 115, p. 1021).—The author constructed an apparatus for preparing calcium chlorid milk serum, which will enable those who do not possess a refractometer to calculate the refractive index of a calcium chlorid milk serum from the specific gravity figure. A table for this purpose is appended. The author does not believe that this method can supplant the refractometer entirely.

The electrical conductivity of milk and the application of this principle for detecting the addition of water and the addition of electrolytes, R. Binachi (Rev. Gén. Laïl, 8 (1910). No. 18, pp. 417–425; 8 (1911). No. 19, pp. 433–449).—It appears from this work that an absolutely fresh and pure milk
has a constant electrical conductivity. When the milk is watered the electrical conductivity diminishes. Sodium bicarbonate, sodium carbonate, borax, and boric acid increase the conductivity, and in proportion to the amount of electrolytes added.

The method is described as easy and rapid of execution. The constants established for 36 samples of milk were the following: Sheep's, 49.43 to 51.72 (average \( K_e=30.40\times10^{-4} \)); goat's, 47.01 to 49.96 (average \( K_e=40\times10^{-4} \)); cow's, 47.57 to 49.78 (average \( K_e=48.70\times10^{-4} \)).

Table for obtaining the specific gravity of milk from the milk-ammonia mixture, W. D. Kooper (Milchzie., Zentbl., 6 (1910), No. 12, pp. 539-553).—The specific gravity of curdled milk is determined by adding a definite amount of ammonium hydrate and determining the specific gravity of the liquid. The specific gravity of the original milk is found by the formula \( S' = \frac{(M+A)\cdot S''-A\cdot S'''}{M} \), where \( S \) is the specific gravity of the milk, \( S' \) the specific gravity of the milk-ammonia mixture, \( S'' \) the specific gravity of the ammonia, \( M \) the volume of milk in cubic centimeters, and \( A \) the volume of ammonia in cubic centimeters.

A table is appended for shortening some of the calculations involved. See, also a previous note (E. S. R., 23, p. 308).

Testing for the calcium sucrate in sterilized milk and cream, W. Eichhorn (Milchzie., Zentbl., 6 (1910), No. 12, pp. 536-537).—The author believes the best method to be the determination of the so-called lime residue figure, because the Cotton number as modified by Baier and Neumann (E. S. R., 21, p. 12) is unreliable.

Determination of fat in cheese by the hydrochloric acid method, H. Höfft (Chem. Ztg., 34 (1910), No. 150, pp. 1343, 1344).—The comparative results obtained in these tests show that neither the concentration of the acid used, nor whether alcohol was employed or not, had any influence on the ultimate results. The cheeses examined were Tilsiter, Edam, Camembert, Limmburger, Romadour, and Wilstermarsch. See also previous notes (E. S. R., 6, pp. 15, 16; 16, p. 440; 24, p. 14).

The determination of sucrose in beet-sugar factory products by Clerget's process, using invertase as hydrolyst. J. P. Ogilvie (Jour. Soc. Chem. Indus., 30 (1911), No. 2, pp. 62-64).—After discussing the various sources of error with the method, particularly when the saccharine substance is improperly defecated, the author concludes that "if in determining the sucrose in beet molasses by Clerget's process invertase be used as hydrolyst, distinctly higher results are then obtained than with the ordinary Herzfeld modification in which concentrated hydrochloric acid is used as hydrolyst. But if in operating the Herzfeld process the error due to the influence of the optically active nonsugar substances be obviated by using the direct acid polarization instead of the usual alkaline (basic lead acetate) polarization, then the results do not differ appreciably from those obtained by means of invertase. From this the fact would appear to be established that invertase is a selective hydrolyst, inverting only the sucrose (and raffinose also, if present), without at all affecting the nonsugar bodies.

"The Pellet method of obviating the error due to the influence of the optically active nonsugars, by taking the direct polarization in a solution made acid by sulphurous acid, gives the same results as the method proposed by Andrlik and Stančk in which the concentrated hydrochloric acid and urea are used, besides having certain other apparent advantages. As a practical method, Pellet's sulphurous process is now recommended as preferable to the Andrlik and Stančk procedure, by reason of its greater ease of manipulation and several other apparent advantages."
Determination of cane sugar and raffinose, E. Sallard (Ztschr. Ver. Deut. Zuckerindus., 1910, No. 659, II, pp. 1183-1194).—This is a discussion of methods for this purpose, with particular reference to inversion constants and formulas.

In regard to the presence of raffinose in raw beet sugar, L. J. de Whalley (Ztschr. Ver. Deut. Zuckerindus., 1910, No. 659, II, pp. 1194-1198).—The author points out that many crude beet sugars examined by him contained very appreciable amounts of raffinose. The formula employed for the purpose was Herzfeld's.

In regard to a uniform method for determining the dry substance in sugarhouse products with the immersion refractometer, V. Staněk (Ztschr. Zuckerindus. Böhm. 35 (1911), No. 4, pp. 187-204).—For this work the author recalculated Wagner's tables to show the relation between the degrees on the refractometer scale and the percentage of dry substance in the sugarhouse product as weighed off, and with reference to this amount in 100 cc. of solution. The tables are given in detail, with another one for correcting the variations due to temperature. The method is described in full.

About the estimation of water in raw sugars by the immersion refractometer, V. Staněk (Ztschr. Zuckerindus. Böhm. 35 (1910), No. 2, pp. 57-64).—The author states that this method is more convenient than the polarimetric method. He points out that where the criterions presented in the article are adhered to the limit of error between two tests will be 0.06 per cent of dry substance.

How sugar is tested, J. B. Baker (Sci. Amer., 104 (1911), No. 10, p. 247, figs. 3).—A general description of the use of the polariscop for testing sugars.

The influence which inactive substances have upon the rotation of levulose, N. Wender (Biochem. Ztschr., 30 (1911), No. 5, pp. 357-373).—The results show that the specific rotation of levulose is increased by inorganic acids and organic acids such as oxalic, while acetic acid, alkalis, alcohol, and acetone decrease it. Inorganic salts, such as sodium chlorid, sodium bromid, potassium lodid, and potassium bromid in certain cases increase it, and in others decrease it. No influence was exerted by slightly basic bodies.

In regard to the reaction ratio of aldehyde and keton sugars to Fehling's solution, E. Remy (Apoth. Ztg., 25 (1910), No. 74, pp. 703-705; abs. in Ztschr. Angew. Chem., 23 (1910), No. 43, p. 2327).—According to Fehling, a reduction relation of 1:5 exists between glucose and copper. According to Soxhlet, this is independent of the concentration and subject to slight variations. On the basis of the formula involved in the reaction products of these reductions, the author determined the ratio of glucose and fructose to cuprous oxid as 1:5.3 (fluctuating between 1:4.8 and 1:5.3), and for invert sugar, bises, and cuprous oxd 1:10.6. The relation between pentoses (arabinose) and cuprous oxid is probably the same as the latter.

Staining of glycogens, P. Mayer (Ztschr. Wiss. Mikros. u. Mikros. Tech., 26 (1910), No. 1, pp. 513-522; abs. in Chem. Abs., 5 (1911), No. 6, p. 1118).—Resorcinol-fuchsin, cresol-fuchsin, and rosamin hydrochlorid stain glycogens. The microscopic field has a granular appearance, the granules standing out boldly against a colorless background. Some further experiments with ammonium hydroxyferrigallate and iodin showed that the iodin preparation could not be made stable, but those with ammonium hydroxyferrigallate remained so for quite some time. Glycogen takes ammonium carminate, but the color is not definite enough to be utilized as an identification test.
The iodin reactions for starch, W. Harrison (Proc. Chem. Soc. London, 26 (1910), No. 376, pp. 252, 253; abs. in Jour. Soc. Chem. Indus., 29 (1910), No. 22, p. 1335; Chem. Ztg., 34 (1910), No. 15, p. 126).—From this work it appears that it is unnecessary to have an iodid present when conducting this test. In the presence of salts or some dilute acid, the blue color obtained in the reaction is decidedly darker. On adding alcohol to the solution it takes on a variety of transitory colors which range from violet to yellow, a reversion to the original color being brought about by adding water. By washing iodid starch with pure water, all the iodin can be removed, from which the author concludes that starch plays the rôle of a protective colloid. Under certain conditions it is possible to produce the reaction for dextrins and starch cellulosides with starch, and the author believes that dextrins and starch cellulosides are simply different colloidal states of starch, and do not represent different compounds.

An improved (Scherer) reaction for inosin, E. Skalkowski (Ztschr. Physiol. Chem., 69 (1910), No. 6, pp. 478–481; abs. in Wehnau. Braue., 28 (1911), No. 3, p. 95).—A little of the inosin is placed upon a porcelain crucible cover, dissolved in from 1 to 2 drops of nitric acid (specific gravity 1.2), then 1 drop of a 10 per cent potassium chlorid solution and 1 drop of a 1 to 2 per cent platinic chlorid solution are added, and the solution carefully evaporated by blowing and rotating. Inosin gives a pink to a brick-red coloration.

Contribution to the biochemical detection of glucosides decomposable by emulsion, E. M. Bouquelot (Pharm. Centralhalle, 51 (1910), No. 47, pp. 1086–1089; abs. in Chem. Abs., 5 (1911), No. 5, pp. 967, 968).—A discussion of new methods for studying the activity of emulsion. The glucosid employed was salicin.

Estimation of formic acid, A. F. Joseph (Jour. Soc. Chem. Indus., 29 (1910), No. 26, pp. 1189, 1190; abs. in Chem. Abs., 5 (1911), No. 3, pp. 415, 416).—The method is based on the oxidation of the acid or formate with bromin, and then estimating the amount of hydrobromic acid or bromid produced. This is referred back to formic acid.

Simple method for determining formaldehyde, F. Herrmann (Chem. Ztg., 35 (1911), No. 4, pp. 25, 26; abs. in Chem. Abs., 5 (1911), No. 6, pp. 1158, 1159).—To a glass-stoppered 150 to 200 cc. Erlenmeyer flask, which contains from 4 to 4½ gm. of the formaldehyde solution, add about 3 gm. of ammonium chlorid, and then run in as quickly as possible amid shaking 25 cc. of double-normal sodium hydrate solution. After allowing the mixture to cool at room temperature, add 50 cc. of water which contains 4 drops of a 1 per cent methyl orange solution, and titrate back with a normal solution of sulphuric acid. The difference obtained between the two normal solutions represents the sodium hydrate consumed for the production of hexamethylamintetramin, and when multiplied by 0.06 represents the formaldehyde in grains in the sample. Where much acid is present in the formaldehyde a correction for the acid must be made by titrating with tenth-normal sodium hydrate and against phenolphthalein.

A method for determining free and combined oxalic acid in plants, W. D. McCabe (Pure Products, 7 (1911), No. 3, p. 114).—The method is as follows:

"Dry the substance, usually 150 gm., in a water oven, pulverize and extract with four 25 cc. portions of acidified alcohol (10 cc. concentrated hydrochloric acid to 90 cc. alcohol). In extracting, the alcohol should be poured over the substance, which is heated on the water bath, allowed to stand for half an hour, and filtered. The residue is then transferred from the paper and extracted three more times. Add 5 cc. dilute sulphuric acid to the combined extractions, evaporate to 50 cc. volume, and filter. Exactly neutralize with sodium hydroxid, make strongly acid with acetic acid, add calcium chlorid solution, let stand overnight, filter, ignite, and weigh as calcium oxid."
The determination of free sulphur in condimental feeds, stock tonics and conditioners, G. M. Macnider (Jour. Indus. and Engin. Chem., 3 (1911), No. 1, pp. 33, 44, fig. 1; abs. in Chem. Abs., 5 (1911), No. 5, p. 330).—The author utilizes for this purpose a special apparatus, which consists of a graduated tube 16.4 cm. long and 3 cm. in diameter, with a stopcock fused in the tube at about 5 cm. above the bottom. One gm. of the feed is placed in the tube, 50 cc. of carbon disulphid added, the tube stoppered, and shaken in a shaking machine for 5 hours. The tube is then allowed to stand over night and 20 cc. of the carbon disulphid extract is drawn off into a 450 cc. Erlenmeyer flask by way of the glass stopcock. The carbon disulphid in the Erlenmeyer flask is evaporated off, the residue dried in a water oven, and the residual sulphur taken up with sodium hydrate. The solution is diluted, the sulphur oxidized with a stream of chlorin, the solution then acidified, boiled to discharge free chlorin, filtered, and the sulphur determined as barium sulphate by precipitation.

Estimation of nicotin in concentrated tobacco juices, H. Ulex (Chem. Ztg., 35 (1911), No. 14, p. 121; abs. in Analyst, 36 (1911), No. 321, p. 153).—Ten gm. of the sample are weighed out in a porcelain dish and diluted with from 1 to 3 cc. of water. A mixture of 1 part of soda lime and 5 parts of calcined gypsum is then mixed with the liquid in sufficient quantity to produce a coarse powder. This is ground in a mortar with gentle pressure, and is passed through a fine sieve with about 220 meshes per square centimeter. The particles remaining on the sieve are again ground with a little more of the mixture, and the process repeated until the whole has been sifted. In mixing the liquid with the soda lime, the quantity taken should be such that all tendency to heating is avoided.

The total mixture will now amount to about 50 gm.; the ammonia compounds will be decomposed and volatilized, and the free nicotin remain behind. The elimination of the ammonia is completed by exposing the powder over sulphuric acid in a desiccator for about an hour. The nicotin is then distilled in a current of steam, using a tin flask of about 3 liters' capacity. This is charged with 1.5 liters of water heated almost to boiling; the dry powder is then introduced quickly, together with from 3 to 4 gm. of potassium or sodium hydroxids and 4 gm. of paraffin wax to prevent frothing. The flask is connected with the condenser and 1 liter is rapidly distilled off. Distillation is then interrupted, and 1 liter of boiling water is added to the contents of the flask, a second liter of distillate being collected in a separate vessel. The nicotin in the distillates is determined by titration with half-normal hydrochloric acid, using litmus as an indicator.

The method, according to the author, gives good results, and no evaporation of nicotin takes place during the elimination of the ammonia in the manner described. While it appears to yield higher results than some of the methods depending on extraction, this, according to the author, is due to the incompleteness of the extraction, and not to a fault in the method described above.

Determination of nicotin in concentrated tobacco juices, J. Schroeder (Chem. Ztg., 35 (1911), No. 4, p. 30).—In this work the author points out the discrepancies which occur when various methods are utilized for the determination of nicotin in tobacco extracts, sheep dips, etc., and describes the Ulex method noted above, which gives decidedly higher results. He criticises the preference of Porchet and Regis (E. S. R., 22, p. 515) for the Toth method. See also a previous note (E. S. R., 25, p. 16).
In regard to the determination of nicotin in concentrated tobacco juices, R. Kissling (Chem. Ztg., 35 (1911), No. 22, p. 299).—This is a criticism of the Ulex method, noted in the abstracts above. The author does not consider the method a good one.

Karite and its products, P. Ammann (Agr. Prat. Pays Chauds, 9 (1909), No. 81, pp. 550-559; 10 (1910), No. 82, pp. 50-62).—After discussing the geographical distribution of the plant (Butyrospermum parkii) and the use of shea butter, the author gives the details of the manufacture of shea butter and the results of the analysis of the product as obtained by various methods and from various localities in the Sudan. The purification and transportation of the product are also considered.

Malt vinegar and maize vinegar, C. F. Juritz (Agr. Jour. Cape Good Hope, 37 (1910), No. 6, pp. 717-736).—After describing the various standards set up for cider, malt, and maize vinegar in the United States, Great Britain, and Cape Colony, the author discusses the present status of malt vinegar in Cape Colony and utilizes the results of numerous analyses to illustrate the various points.

He concludes that "if the manufacture of maize vinegar is ever to become a large local industry, two alternatives are open, either (a) the use of maize grits must be studiously avoided in the general interest, lest the market be flooded with the products of fermentation of damaged rice—products which would be chemically indistinguishable from vinegar produced from maize grits, but would possess a sufficiently evident distinction from whole maize vinegar, or (b) definite standards will have to be laid down by legislation, discriminating more clearly than at present between vinegar prepared from whole grain containing a certain proportion of phosphates and nitrogen, and vinegar made from more exclusively starch materials like rice or maize grits."

Yeast cultures for the fermentation of fruit juices, H. J. Alwood (Pure Products, 7 (1911), No. 1, pp. 16-22, fig. 1).—In this article the author points out the advantages of utilizing pure cultures of yeast for preparing ciders and wines. The methods of preparing pure yeast cultures are described.

The use of chicory for producing alcohol, W. Donfelt (Ztschr. Spiritus-indus, 34 (1911), No. 8, p. 93).—These tests with chicory (Cichorum intybus) show that this raw material can not be looked upon as a favorable source of alcohol.

Foreign varieties of tomato conserves (Pure Products, 7 (1911), No. 3, pp. 133-136).—This article discusses the manufacture of tomato purée, tomato catsup, English tomato sauce, tomato jam, tomato sirup, and whole tomato conserves. The products of the Romance countries are particularly considered.

Tomato-seed oil, P. Accomazzo (Indus Chinn., 10 (1910), pp. 369, 361; abs. Jour. Soc. Chem. Indus., 30 (1911), No. 2, p. 95).—The manufacture of tomato preserves is an important industry in Italy, and the author discusses the question of utilizing the residue for the manufacture of tomato-seed oil.

According to statistics published by the Chamber of Commerce of Parma, in this province alone about 850,000 quintals (83,000 tons) of tomatoes are treated per annum, yielding, after the removal of water by simple pressing, or by utilizing waste heat available in the preserve factory, from 40,000 to 42,000 quintals, of which from 10,000 to 12,000 quintals correspond to skins and the remainder to seeds.

Special tests showed that tomato seeds yield 18 per cent of oil on cold pressing and 20 per cent by extraction. The oil has the specific gravity 0.920, saponification value 184, and iodin value 118. It has rather pronounced drying properties and would probably be useful as an ingredient of oil varnishes, and as a burning oil. See also previous notes (E. S. R., 24, p. 311).
Technology of impregnation. T. Koller (*Die Impregnirungs-Technik, Vienna and Leipzig* [1911], pp. XVI+442, figs. 45).—After discussing the various materials used for impregnation, the author in this book describes in detail the impregnation of woods for the purpose of protecting against rotting, impregnation of miscellaneous materials for rendering them impervious to water, impregnation for the purpose of making certain commodities and miscellaneous articles fireproof, impregnation of fluids and gases, impregnating machinery, and special methods of impregnation.

**METEOROLOGY—WATER.**

Climatic influences in the economic development of Australia, E. Van Cleef (*Bul. Geogr. Soc. Philadelphia*, 8 (1910), No. 4, pp. 1-26, maps 3).—The author shows that as regards climatic characteristics Australia is quite sharply divided into (1) a hot, dry, interior province, and (2) a more humid subtropical coastal province, and that distribution of population and agricultural production very closely coincide with these climatic divisions. The limited possibilities of reclamation by means of irrigation are especially emphasized and a very close relation between economic development and occurrence of droughts is pointed out.

In view of the fact that the mineral resources of the country are limited and manufacturing must therefore remain at a minimum, "the country must be absolutely dependent upon the soil. The soil is the prime factor in bringing returns to the people. The production from the soil is dependent upon the climate, especially where irrigation is impossible as it has practically proven to be in Australia. ... The discovery of a method whereby irrigation may be possible will mean Australia's freedom from the destructive drought and will offer opportunities for continued progress, on a limited scale.

A short bibliography of the literature bearing upon this subject is given.

**Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and C. M. Damon (Massachusetts Sta. Met. Buls 267, 268, pp. 3 each).—Summaries are given of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1911. The data are briefly discussed in general notes on the weather of each month.**

**The disinfection of water. R. G. Perkins (Mo. Bul. Ohio Bd. Health, 1 (1911), No. 3, pp. 72-78).—The more efficient methods for this purpose recently proposed are briefly described, and a short bibliography of the main sources of information regarding them is given.**

**Nonrelation of the natural ice supply to typhoid fever and dysentery, H. W. Hill (Cold Storage and Ice Trade Jour., 30 (1910), No. 6, pp. 33-35).—In this article the position is taken that the danger of transmission of these diseases by means of ice has been very greatly exaggerated.**

**The handling and utilization of sewage sludge, A. Elsner (*Die Behandlung und Verwertung von Klärschlamm, Leipzig*, 1910, pp. VIII+87, figs. 30).—This pamphlet deals in a comprehensive way with the amount and character of sludge obtained in different processes of sewage disposal and with different methods of handling and using the sludge. A section is devoted to the use of sludge as a fertilizer, both in wet and dry condition, and in mixture with absorbent materials. This discussion is confined to statements regarding the experience at various places in the use of sludge as a fertilizer and does not pass upon the economy of this method of utilization.**

**Night soil—a valuable manure, G. K. Kelkar (Dept. Agr. Bombay Bul. 34, 1909, pp. 12).—Various methods of handling night soil are described, and**
experiments with poudrette prepared in different ways in comparison with barnyard manure, oil cake, and sewage effluents of different kinds are reported. It is stated that "of all the systems employed for the manufacture of poudrette, the one in which the night soil and town sweepings are mixed with a top layer of earth for weighting down the whole mass appears to be the best suited for adoption by the municipalities where the question of disposing of both these substances in quantities is important."

Analyses of poudrettes prepared by different processes are reported, showing nitrogen varying from 0.8 to 1.68 per cent, phosphoric acid from 1.57 to 4.1 per cent, and potash from 2.22 to 5.33 per cent, with a moisture content ranging from 4.64 to 15.70 per cent.

In experiments on corn, sorghum, sugar cane, guinea grass, alfalfa, and other forage plants, poudrette proved more effective than barnyard manure. The residual effect of the poudrette was observed 10 years after application.

[Experiments with night soil], T. F. Main (Ann. Rpt. Dept. Agr. Bombay, 1909-10, pp. 31, 32).—Good results from direct applications of night soil to cotton and from its after effects on succeeding crops for 6 years are reported. It was more effective, prompt in action, and profitable than barnyard manure.

SOILS—FERTILIZERS.

A wax seal method for determining the lower limit of available soil moisture, L. J. Briggs and H. L. Shantz (Bot. Gaz., 51 (1911), No. 3, pp. 210-219, figs. 2).—The method proposed "consists in growing the plants in a small glass pot, evaporation from the soil surface being prevented by means of a seal of wax which is melted and flowed over the soil surface. In the case of monocotyledons, this wax seal can be applied immediately after planting the seeds, and the seedlings will grow readily through the wax, forming a perfect seal around the stems. In the case of dicotyledons, the wax, which is usually a mixture of paraffin and vaseline having a low melting point and low heat conductivity, can be melted and flowed around the stems of the seedlings without injury. During growth, the pots are kept immersed in a water bath to avoid condensation of the soil moisture on the pot walls."

The water in this bath is stirred constantly to keep the temperature uniform, and a temperature of about 70° and a relative humidity of about 85 per cent are maintained. The amount of water added to the soil at the beginning depends upon the texture and will vary from 5 per cent for sand to 30 per cent for clay. As soon as the plants show unmistakable signs of wilting the moisture in the soil in the pots is determined and this is taken as a measure of the non-available soil water.

Tests of the method with Kubanka wheat seedlings indicate that "the probable error of the mean of the determinations from 12 pots or more does not usually exceed 0.1 per cent of actual soil moisture, which is fully comparable to the accuracy with which the soil itself can be defined through its physical properties."

In these tests the mean nonavailable moisture was 2.59 per cent in fine sand, 9.66 per cent in fine sandy loam, and 16.3 per cent in clay loam. The method is stated to be particularly adapted to the study of transpiration.

Contributions to our knowledge of soil fertility, I. R. Greig-Smith (Proc. Linn. Soc. N. S. Wales, 35 (1910), pt. 4, pp. 808-822B).—In these investigations the author found, by means of cultures of Bacillus prodigiosus in soil extracts filtered through paper and porcelain filters, that bacteriotoxins were unquestionably present in the soils experimented with and that these either killed or restricted the growth of bacteria which had been added to the extracts.
Various solvents (carbon bisulphid, chloroform, and petroleum ether) extracted from garden soil a wax, or group of waxlike bodies, for which the name "agricere" is proposed. The results are summarized as follows:

"Water extracts from soil a substance which is filterable through porcelain, and which is toxic to bacteria.

"The toxicity is made evident by the retardation of growth, or by the destruction of the bacteria.

"The toxin is destroyed by heat, by sunlight, and by storage. It slowly disappears from air-dried soil, and rapidly decays in aqueous solution. It is not destroyed by salts, such as sodium chloride, potassium, or magnesium sulphate.

"Soils vary in the amount of toxin they contain, good soils containing less, poor soils more.

"The particles of soil are covered or 'waterproofed' with soil wax or 'agricere,' which consists of a mixture of saponifiable and unsaponifiable bodies.

"The wax solvents (volatile disinfectants) alter the distribution of the agricere by carrying it to the surface of the soil, and causing it to be segregated on the points of the soil particles.

"With the removal of the 'waterproofing' the soil nutrients are more easily dissolved by soil water, and attacked by bacteria."

On the importance of humus bodies, II. Fischer (Fühling's Landw. Ztg., 60 (1911), No. 3, pp. 73-83).—This article reviews the present knowledge regarding the composition and action of humus compounds in the soil, especially in their bearing upon bacterial activity.

The new science of the soil, W. H. Beal (Sci. Amer., 104 (1911), No. 7, pp. 168, 169, 186, 187, figs. 6).—This is a brief review of some of the more recent advances in chemical, physical, and bacteriological investigation of the soil.

The importance of soil maps to soil science and agriculture, E. Blanck (Fühling's Landw. Ztg., 60 (1911), No. 4, pp. 121-155).—This article reviews the development and present status of soil mapping, indicating its scientific and practical value.

Soils of New South Wales, III, H. I. Jensen (Agr. Gaz. N. S. Wales, 22 (1911), No. 1, pp. 27-35).—This article deals with the origin, classification, and composition of these soils and compares them with the north coast soils of New South Wales previously reported upon (E. S. R., 23, p. 521; 24, p. 618).

It is stated that owing to the higher rainfall of that region the north coast soils are relatively richer in organic matter and poorer in mineral plant foods than the south coast soils. The basalt soils, especially, are much leached and contain a low percentage of lime. The quality of the soils of both the northern and southern districts depends upon the geological formations from which they are derived, and diminish in productivity in the following order: Alluvial; basalt; diorite and basic (hornblendie) granite; shale and mudstone; phyllite, schist, and slate; acid (siliceous) granite; and sandstone.

The average composition of the north coast and south coast soils is given in the following table:

<table>
<thead>
<tr>
<th>District</th>
<th>Moisture</th>
<th>Volatile matter</th>
<th>Nitrogen</th>
<th>Lime</th>
<th>Potash</th>
<th>Phosphoric acid</th>
</tr>
</thead>
<tbody>
<tr>
<td>129 South coast soils</td>

<td>10.36</td>
<td>0.086</td>
<td>0.231</td>
<td>0.217</td>
<td>0.125</td>
</tr>
<tr>
<td>224 North coast soils</td>
<td>6.29</td>
<td>13.18</td>
<td>0.086</td>
<td>0.256</td>
<td>0.173</td>
<td>0.178</td>
</tr>
</tbody>
</table>
The higher percentage of potash in the south coast soils is attributed to the predominance of granite in that region. The author believes that in order to interpret a soil analysis correctly, the position of the soil, its geological formation, and the climate of the district must be known.

The German moors and their agricultural importance, Tacke (Illus. Landw. Ztg., 31 (1911), No. 16, pp. 133-136).—This is a general discussion on the extent and agricultural possibilities of these lands, with a view to stimulating their reclamation.

Moor cultivation in Germany, Oliver (Jour. Bd. Agr. [London], 17 (1911), No. 12, pp. 999-1002).—This article deals briefly with the origin, composition, manuring, and management of upland and lowland moors in Germany, particularly in the region of Hamburg. Special emphasis is laid upon the use of moors as meadows.

The acid content of moor water, K. Endell (Jour. Prakt. Chem., n. ser., 82 (1910), No. 19-21, pp. 414-422; abs. in Chem. Ztg., 35 (1911), No. 10, Repert., p. 37).—Tests showed a decided acidity in the water from a number of moors. This acidity is attributed entirely to free carbon dioxide. The brown-colored humus colloids removed from the water by dialysis were not acid.

The improvement of marsh soils, Luedecke (Ztschr. Landw. Kammer Schlesien, 15 (1911), Nos. 9, pp. 266-272; 10, pp. 300-306; 11, pp. 333-338).—The author discusses the fertilizer constituents, agricultural value, and reclamation of these soils. He is of the opinion that stock farming, whereby much of the land could be sown to grass and clover, is the best use to make of the lands, and gives data showing the profits that may be obtained per acre under such a system of farming. Methods of cultivating and seeding are outlined.

The value of different crops as green manures, A. D. Hall (Jour. Bd. Agr. [London], 17 (1911), No. 12, pp. 969-971).—Attention is called to results of experiments at Rothamsted on heavy soils which do not agree with those of experiments at Woburn on light soils as to showing that mustard is more effective as a green manure for wheat than vetch. In the Rothamsted experiments the yield and nitrogen content of wheat were uniformly higher following crimson clover and vetch than after mustard or rape.

The fisheries and the guano industry of Peru, R. E. Coker (U. S. Dept. Com. and Labor, Bur. Fisheries Bul. 28 (1908), pl. 1, pp. 333-365, pls. 6).—The fisheries and the guano industry are discussed together in this article, as strictly the guano may be considered a fishery product, and it is impossible to separate the two in protective and regulative measures, which it is the main purpose of this article to discuss. The guano-producing birds are described, and the principles which should underlie regulations for the protection of the birds and the extraction of the guano are set forth.

Bat and bird guanos in India, I. H. Burkill (Agr. Ledger, 1911, No. 1 (Anim. Prod. Scr., No. 3), pp. 1-9).—The character, composition, extent, and exploitation of guano deposits in different parts of India are briefly discussed in this article. It is shown that the guanos are very variable in composition, but are generally comparatively rich in phosphoric acid and poor in potash and nitrogen. As a rule the deposits are too small in extent to be of any except local interest.

Report of experiments with nitrogenous manures, T. Milburn and R. C. Gaut (County Council Lancaster, Ed. Com., Agr. Dept., Farmers' Bul. 20, pp
SOILS—FERTILIZERS.

Comparisons of ammonium sulphate, sodium nitrate, and commercial calcium cyanamid and calcium nitrate on oats, mangel-wurzels, and potatoes are reported, the results indicating that equal amounts of nitrogen supplied by these four nitrogenous fertilizers are equally effective for crop production. The calcium cyanamid is subject to the objections that it is very light, dusty, and troublesome to apply, and may cause injury to young and tender parts of plants. The calcium nitrate must be handled carefully on account of its moisture-absorbing property or it will become sticky and difficult to apply.

The utilization of the nitrogen of the air, C. FRENZEL. (In Fortschritte der Naturwissenschaftlichen Forschung. Berlin and Vienna, 1911, vol. 2, pp. 193-272, figs. 17).—Investigations and the development of industrial processes relating to the artificial fixation of the nitrogen of the air are fully reviewed, with bibliographies of the more important literature bearing upon different phases of the subject.

The preparation of nitric acid from the air by the Pauling process, J. VAN DERPOL (Houille Blanche, 10 (1911), p. 5; abs. in Metallurgy, and Chem. Engin., 9 (1911), No. 4, pp. 196-198, figs. 4; Ztschr. Elektrochem., 17 (1911), No. 11, pp. 431-434, figs. 4).—The installation and operation of this process at La Roche de Ramon, France, are described. Nine 600-kilowatt furnaces are now in operation, but it is stated that the furnaces will be enlarged to 1,000-kilowatt capacity.

Use of cyanamid in France, D. B. MASON (Daily Cons. and Trade Rpts. [U. S.], 11 (1911), No. 90, pp. 264-266).—This report refers to the steadily increasing use of calcium cyanamid in France and to tests of the material as a fertilizer for oats, wheat, corn, and potatoes. It is stated that the cyanamid used in France in 1909 and 1910 cost from $1.84 to $1.93 per hundred pounds, containing 15 per cent of nitrogen, but that the same material sold for a much lower price in Norway on account of the cheap water power available for its production in that country.

Results of fertilizer experiments with potassium silicate and like substances during 1910, WEIN (Deut. Landw. Presse, 38 (1911), No. 25, pp. 291, 292).—Plat experiments with different crops and at various places are reported, the conclusion being drawn from the results that the fertilizers of this character tested were very effective and gave good returns.

Investigations on the action of ground phonolite, W. KRÜGER ET AL. (Mitt. Deut. Landw. Gesell., 26 (1911), Nos. 10, pp. 111-115; 11, pp. 125-128; 12, pp. 146-158; Mitt. Herzogl. Anhalt. Vers. Stat., 1911, No. 48, pp. 19, pls. 2).—As a result of a series of pot and field experiments with cereals, grass, potatoes, and beets the authors reached the general conclusion that ground phonolite is ineffective and expensive as compared with potash salts.

Fifty years of the German potash industry, P. KRÜSSCHE (Chem. Indus. [Berlin], 33 (1911), No. 7, pp. 173-182).—This is a review of the history and present status of this industry, noting especially the investigators who have contributed to the improvement of the industry and the firms now engaged in it.

The fertilizing value of certain phosphatic materials, A. GREGOIRE and J. HENDRICK (Ann. Géombloux, 21 (1911), No. 4, pp. 166-183).—Pot tests of two proprietary so-called precipitated mineral phosphates are reported, showing that these materials were much less effective as fertilizers than pure bicalcium phosphate. Moreover, they contained substances which render them unfit for use in feeding animals.

The production of phosphate rock in 1909, F. B. VAN HORN (U. S. Geol. Survey, Advance Chapter from Mineral Resources of the United States, Calendar Year 1909, pp. 7; abs. in Manufs. Rec., 59 (1911), No. 9, p. 54).—It is stated that the total production of phosphate rock in the United States in 1909 was
EXPERIMENT STATION RECORD.

2,330,152 long tons, valued at $10,772,120, as compared with 2,386,138 long tons, valued at $11,339,124, in 1908. There was an increase in production in Florida but decreases in South Carolina and especially in Tennessee. "Arkansas, Idaho, Utah, and Wyoming were the only other States to produce phosphate rock in 1909. The total production from these States was 0,493 tons in 1900, as compared with 13,111 tons in 1908, a loss of 3,618 tons."

The gypsum industry in 1909, E. F. Burchard (U. S. Geol. Survey, Advance Chapter from Mineral Resources of the United States, Calendar Year 1909, pp. 11).—It is stated that 2,272,785 short tons of gypsum was mined in the United States in 1909, representing an increase of nearly 31 per cent over the production of 1908. Of this amount 49,581 tons was sold for use as land plaster, representing a decided increase in such use over that of the previous year. Gypsum was produced in 16 States and 2 Territories besides Alaska during 1909, the largest production being reported from New York, Michigan, and Iowa.

The rocks and waters of the Roman Campagna with respect to lime, G. de Angelis d'Ossat (Atti R. Accad. Lineci Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 20 (1911), I, No. 4, pp. 253–266).—This is an account of a study of the lime content of the rocks and waters of this region with reference to the rate of solubility of the calcium carbonate of the rocks in water under varying conditions.

Molasses as a fertilizer, G. N. Martin (Internat. Sugar Jour., 13 (1911), No. 17, pp. 153–155).—The author refers to experiments by himself and by Boname (E. S. R., 21, p. 724), indicating marked and profitable benefit from applications of from 400 to 600 gallons of molasses per acre in the furrows from 1 to 2 weeks before planting cane.

On the composition and fertilizing value of peat ash, H. von Feilitzen (Mitt. Liv-Estländ. Bur. Landeskult., Jahrb. 1909–10, pp. 31–34).—Analyses are reported which show variations in lime from 5.79 to 21.04 per cent, with an average of 13.26 per cent; in potash from 0.52 to 2.21 per cent, with an average of 1.16 per cent; and in phosphoric acid from 1.73 to 2.7 per cent, with an average of 2.3 per cent. The average of water-soluble potash was 0.25 per cent and of citric-acid-soluble phosphoric acid 0.96 per cent. It is stated that pot experiments, which, however, have not yet been completed, indicate that the potash and phosphoric acid of peat ashes do not have as great fertilizing value as the same constituents in Stassfurt salts and superphosphate. [Fertilizing materials], F. V. Dareishire and W. Goodwin (Jour. Southeast. Agr. Col. Wyc, 1909, No. 18, pp. 201–207).—Analyses of potassium phosphate, tortoise-shell dust and shavings, ammonium sulphate, bone manures, fish guano, shoddy, and sewage sludge are reported, with brief comments upon their fertilizing value.

Analysis of fertilizers sold in Maryland, H. B. McDonnell et al. (Md. Agr. Col. Quart., 1911, No. 51, pp. 31).—This bulletin reports analyses and valuations of fertilizers examined during September to December, inclusive.

Inspection of commercial fertilizers, P. F. Trowbridge et al. (Missouri Sta. Bull. 91, pp. 391–448).—This report, made in accordance with the Missouri fertilizer law, covers the year ended December 31, 1910, and contains the text of the law, a statement regarding the purchase of fertilizers, a list of fertilizer manufacturers and brands offered for sale by them, a comparison of the valuation of fertilizers of the same guarantied composition, analyses of the fertilizers inspected, and a financial statement.

Analyses of fertilizers, B. W. Kilgore et al. (Bull. N. C. Dept. Agr., 32 (1911), No. 1, pp. 81).—Analyses and valuations of fertilizers collected in North Carolina during the fall season of 1910 are reported, and a list of brands registered for the season of 1910–11 is given.
Commercial fertilizers. E. Fulmer (Washington Sta. Bul. 98, pp. 24)—This bulletin contains the text of the state fertilizer law, a statement regarding the use of fertilizers in Washington, explanations regarding the sources, character, and prices of fertilizing materials, and analyses and valuations of fertilizers inspected during 1910.

AGRICULTURAL BOTANY.

The water balance of succulent plants, D. T. MacDougall and Effie S. Spalding (Carnegie Inst. Washington Pub. 141, pp. 77, pls. 8, dynms. 16).—Attention is called to the fact that many plants have a capacity for absorbing and conducting water far in excess of the amount they give off, the flora of Arizona, Nevada, and Sonora being especially rich in forms which carry a large water balance. A series of observations covering several years has been made for the purpose of determining the amount of the balance, its variations, the factors influencing its volume, the relation of the various proportions of the balance to growth, and the reversible changes to which such plants are subject. The studies were made principally with the giant cactus (Carnegaea gigantea), bisnaga (Echinocactus wislizeni), and some of the common prickly pears (Opuntia spp.).

In the investigations on form alteration and growth of cacti, as shown by previous studies, it was found that the giant cactus not only possesses a structure remarkably fitted for the storage of a large quantity of water, but also, without the slightest interference with the efficiency of its mechanical system, adjusts itself by a change of form to the increased supply taken up from the soil after a rain, and to its diminution during subsequent periods of drought.

The observations in the present paper confirm those relating to the mechanical adjustment of the trunk of the giant cactus and show that insolation is a strong secondary factor operating in conjunction with the water supply and modifying its effects. Changes of air temperature were found to produce slight expansion and contraction of the trunk, but in most cases the minor changes were obscured by those caused by variations in soil moisture.

Discussing the growth of the giant cactus, or sahuaro, it is said that for a few years growth is apical, the increments of succeeding years increasing in diameter until the trunk attains the full thickness, which is afterwards maintained throughout life. The average yearly growth in height of individuals is between 10 and 12 cm., and from the data collected it appears that a giant cactus requires approximately 100 years to attain a height of 10 meters.

The percentage of water in the healthy sahuaro ranges from 75 per cent of the fresh weight in its lower part to more than 90 per cent in its upper part. A plant 6 meters high absorbed and stored approximately 412 liters of water between November, 1906, and March, 1907, in addition to the amount transpired. Transpiration from the trunk is slow, but is quite rapid from flowers and flower buds, the average transpiration of a fully opened flower being at least 850 mg. an hour in full sunlight.

Comparative studies with Echinocactus showed that its structural features are essentially the same for mechanical adjustment as those of the giant cactus. Some differences, however, are noted in mode of growth. In the Opuntia the mechanical adjustment is provided in a somewhat different way, the joint swelling or shrinking with the amount of water received or lost.

In discussing the water balance it is shown that these succulent plants can lose a large amount of the water contained in them without appreciable injury, practically all specimens surviving for a year after the water supply had been cut off. Weighings were made of a number of specimens, and after a rather
rapid loss there followed a period of very slow loss of water. In addition to the mechanical adjustment to prevent loss of water there is some indication of an increasing acidity of the cell sap, which possibly aids materially in reducing transpiration, although the present investigation does not demonstrate such a relation.

A discussion of the water balance and its relation to desert flora is given.

A new method for estimating the gaseous exchanges of submerged plants, F. F. Blackman and A. M. Smith (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. B 565, pp. 374–388, figs. 2).—A method is described for estimating the gaseous exchanges of submerged plants, which consists essentially of passing a continuous current of water containing dissolved carbon dioxide over the assimilating plant and determining the difference in the carbon dioxide content of the water before and after contact with the plant as a measure of the assimilation taking place.

On assimilation in submerged water plants, and its relation to the concentration of carbon dioxide and other factors, F. F. Blackman and A. M. Smith (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. B 565, pp. 389–412, figs. 2).—In a previous paper (E. S. R., 18, p. 923) it was shown that assimilation by green leaves was determined by the limiting factors of light, temperature, and carbon dioxide. In the present paper an account is given of a quantitative study of assimilation in submerged plants along similar lines, the studies being made with several species of aquatic plants with the apparatus described above.

The nature of the relation between assimilation and the environmental characters of carbon dioxide, light intensity, and temperature was found to be such that the magnitude of assimilation in every combination of the factors was determined by some one of them acting as the limiting factor. When so limited, an increase of that factor was found to bring about an increase in the magnitude of assimilation. As an example the authors found with constant light and temperature, but with increasing carbon dioxide content of the water, that photosynthesis increased up to a certain degree, beyond which there was a sudden drop unless more light or a higher temperature was employed.

Studies on the relation of the living cells to the transpiration and sap flow in Cyperus, II, J. R. Overton (Bot. Gaz., 51 (1911), No. 2, pp. 102–120, figs. 2).—In a previous paper (E. S. R., 24, p. 626) an account is given of the effect on transpiration of killing portions of stems with steam or hot wax, and in the present paper experiments are described with various poisons, the stems being killed with xylol, picric acid, alcohol, copper sulphate solution, corrosive sublimate, etc.

The experiments with the poisons show that the different kinds influence the subsequent rate of evaporation of water from the plants, and that in many cases the new rate far exceeds the normal transpiration of a plant of the same age and superficial area. It seems certain that in the case of plants poisoned throughout, the elevation of water in the stems and its evaporation from the leaves in larger quantities than normally occurs in living plants depend purely upon physical processes.

Summarizing the results of the different experiments the author shows that no matter how long the section killed by steam may be, the leaves never wither quite so quickly as those cut and not placed in water, but kept under the same conditions of light, temperature, and moisture. A certain amount of water is raised through the steamed portion, but it gradually diminishes until the leaves become air dry. Diminution in the water supply is partially due to a blocking of the vessels with a gumlike substance, which probably owes its origin to the disorganization of the contents of the sieve tubes caused by heating the stems.
The withering of the leaves is believed to be caused more by the action of the deleterious substances introduced into them from dead cells than from lack of water, and the leaves of rooted plants grown in nutrient solutions containing sterilized decoctions of the same plant droop in from three to five days, and become dry in from seven to eight days.

In experiments in which portions of the stems were killed with picric acid, alcohol, or copper sulphate, sufficient water was found to ascend through the poisoned portions to continue the transpiration for a comparatively long period and to allow the development of new branches. Picric and chromic acids and corrosive sublimate greatly accelerated the amount of water evaporated in poisoned plants.

A bibliography of literature cited is given.

The temperature coefficient of the duration of life of barley grains, T. H. Goodspeed (Bot. Gaz., 51 (1911), No. 3, pp. 220-224).—The temperature coefficient for the duration of the life of barley grains was determined by subjectsing different lots of seed to temperatures varying from 55° to 70° C., after which the vitality of the seed was tested. The time in minutes required for a given temperature to act in order to inhibit subsequent growth was taken as the duration of life under the conditions of the experiment.

At a temperature of 55° from 65 to 70 minutes’ exposure was required to destroy the germinative ability of barley seed, while at 70° an exposure of from 1½ to 2 minutes destroyed it. The average temperature coefficient for every degree centimeter was 1.27, or about 11 for a temperature interval of 10°.

The rôle of chlorophyll and light in the transformation of the carbon dioxide and aqueous vapor of the air, A. Dubosc (Rev. Gén. Chim., 13 (1910), Nos. 15, pp. 268-270; 17, pp. 273-281; 18, pp. 295-303; 19, pp. 316-320; 21, pp. 331-335).—A résumé is given of various opinions regarding the functions of chlorophyll and light in decomposing and transforming the carbon dioxide and aqueous vapor of the air, the author supplementing the published results of others by comments and observations of his own.

The respiratory energy of plants cultivated in different degrees of light, E. Rosé (Rev. Gén. Bot., 22 (1910), No. 262, pp. 385-398, pl. 1).—A study was made of the respiratory energy under different degrees of illumination of peas, representing plants accustomed to strong light, and of Trichium scorodonum, a shade plant. The intensity of the respiration was found to vary with the different plants, with different degrees of illumination, and with different stages of growth for the same plant.

The portion of the spectrum influencing photosynthesis, P. A. Dangeard (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 5, pp. 277-279).—By means of a Nernst lamp, which was used day and night for a period of two months, the author has studied the effect of different portions of the spectrum on the photosynthesis of an alga, Chlorella sp.

At the end of about eight days there was a distinct band of green growth, which occupied the principal absorption band of chlorophyll, and this corresponded to absorption band I of chlorophyll, which has a wave length of from 670, to 635, according to Jost. The spectrum of growth of the alga extended from the limits of the infra-red nearly to line II in the violet, all the rays occurring within these limits having a part in photosynthesis. Beyond this there was little activity except in the region of absorption bands II and III of chlorophyll.

Leaf decay and autumn tints, P. Q. Keegan (Chem. News, 102 (1910), No. 2657, pp. 213, 214).—In a previous communication the author called attention to the relation between the ash of leaves and their autumn tints. Subsequent study has shown a connection between the vitality of the leaves and their
coloration, the connection apparently being through the albuminoid content of the leaves. An examination of a number of species showed that in some the quantity or ratio of the albuminoids of the leaf remains permanent from July until the time when the chlorophyll begins to disappear, while in others the ratio becomes gradually and permanently less with the advance of the season.

In general those leaves in which there is a marked reduction in the albuminoid content become red in autumn, while those in which the albuminoid content remains nearly constant are brown. Some exceptions are noted to this, particularly in the leaves of oak and beech, which are occasionally bright red, and this is explained by different physiological activity, there being a transfer of the albuminoid due to the prolonged vegetation of the tree. The relation between the red coloring and the albuminoid content suggests that there is probably a connection between the diminution of the albuminoid matter and the development of the vivid crimson or purple coloration.

The influence of acidity on germination, Mlle. G. Promsy (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 8, pp. 450–452; abs. in Rev. Sci. [Paris], 49 (1911), I, No. 9, p. 282).—The author found that different acids not only increased the growth of various plants, some more rapidly than others, but also stimulated a greater production of dry matter, when determined at the end of germination after the plants had become green.

The organic acids, of which there were a number, are held to contribute to the nutrition of the plants. Germination was accelerated in proportion to the different organic acids used and the species of plant experimented upon. The author claims that the favorable action often attributed to bases can not be considered as due to the neutralization of the acid of the plant.

The use of solutions of potash to determine the germinative faculty of seeds, P. Lesage (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 10, pp. 615–617).—The author describes a method for determining the germinative ability of seeds by placing them in solutions of caustic potash. Varying dilutions of a normal solution were used, and for different kinds of seed it was found that the strength of solution had to be varied.

Nonviable seed was found to discolor the solution within a few hours, while sound viable seed did not. This method was worked out for the seeds of cress, but it has been tested on a number of other kinds of seed and found to apply to many of them.

The effect of the activation of the atmosphere by radium emanations on the germination and growth of plants, G. Fabre (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 6, pp. 187, 188).—The author reports the effect of radium emanations on the germination and development of Sterigmatocystis nigra, Mucor mucedo, and Linum catharticum.

With Sterigmatocystis the germination of the spores on acid gelatin was retarded by the emanation of radium of high potency. The optimum dose of one-half microcurie per cubic centimeter of air retarded germination for the first three days, but on the fourth day the growth equaled that of check cultures. With a double quantity the germination was greatly reduced and the growth of the mycelium was retarded. Similar results were obtained with Mucor.

The germination of seeds and development of the seedlings of Linum were favored by increasing emanations up to 1.5 microcuries for 2 liters of air. The growth was retarded by increasing the amount of emanation, and germination was retarded where it amounted to 40 microcuries per liter of air.

Nitrogen and chlorophyll in galls and etiolated leaves, M. Molliard (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 5, pp. 274–277).—A study is reported of the nitrogen content of normal leaves and of galls formed by various insect parasites on a number of species of plants, in which it was found
that the proportion of soluble nitrogen to total nitrogen increased in the abnormal growths due to the presence of the insects. An examination of etiolated leaves showed a similar condition, and attention is called to the possible correlation between the increase of soluble nitrogenous materials and the diminution of chlorophyll.

Some experiments on the utilization of ammonium salts by green plants, E. Pantanelli and G. Severini (Staz. Sper. Agr. Ital., 43 (1910), No. 6, pp. 449–544).—The authors review quite fully the work of other investigators on the comparative fertilizing value of different forms of nitrogen and the conditions which they produce in soils, and report the results of experiments on the utilization of different ammonium salts by green plants grown in sterilized liquid cultures, in sterilized soils of different structure and each having a different absorbing power, and in soils under normal crop conditions. The salts used were sodium nitrate (for comparison), ammonium tartrate, nitrate, sulphate, and chloride, triammonium phosphate, and ammonium magnesium phosphate, while wheat, rice, mustard, corn, and flax were the plants used.

Detailed tabulated data are given of the resulting acidity or alkalinity of the culture media for the various ammonium salts used during the period of growth of the plants, both in the water and pot cultures. The amounts of organic, ammoniacal, and nitrate nitrogen obtained or used during the growing period of the plants are recorded. The general effects of each salt on the growth of the different plants are also noted.

It was found that in liquid cultures, under conditions in which nitrification was excluded, certain ammonium salts are able to act as a source of nitrogen food for green plants. A rapid absorption of the ammonium cation induces an acidification of the nutritive liquid, which reaches a maximum during the first period of growth for those salts of ammonium derived from strong acids, such as sulphuric, hydrochloric, nitric, and phosphoric acids. If the anion is absorbed rapidly, as is the case with the nitric and phosphoric anions, after the first week of growth the external acidity diminishes and the plants grow vigorously. By using an ammonium salt which is only slightly soluble, such as ammonium magnesium phosphate, this danger of acidification is avoided. Moreover, the absorption of the ammonium is thereby much decreased, giving the plant time to utilize it in the best possible manner for the production of organic substances and of albuminoids. Especially is this true of wheat, maize, and rice. In sterile soils where nitrification is excluded, the different salts of ammonium act differently under the influence of two principal factors, viz., the diverse absorbing power of the soil for the ammonia, and the presence of lime in the soil in sufficient quantities.

Briefly, the authors conclude that the inferiority usually attributed to ammonium sulphate as compared to nitrate of soda as a source of nitrogen results from irrational application to the soil or to crops to which it is not suited, and does not justify a general depreciation of ammonium salts as a source of nitrogen food for green plants; that ammoniacal nitrogen has a coefficient of utilization for the formation of organic nitrogenous compounds superior to that of nitrate nitrogen; and that the utilization of a salt of ammonium depends upon the relative rapidity of the absorption of its two ions.

Investigations on nitrogen assimilation in green leaves, R. Otro and W. D. Kooper (Landw. Jahrh., 39 (1910), No. 6, pp. 900–1004).—The author gives the results of experiments with the leaves of *Aesculus hippocastanum* as to their ability to fix free nitrogen.

Fresh leaves were cut from the plant and the stems placed in distilled water. Tests were then made for the nitrogen content of these leaves every morning.
and evening. It was found that instead of the evening tests showing a greater amount of nitrogen, they showed less than similar leaves tested in the morning. The conclusion is drawn, therefore, that the leaves of nonleguminous plants do not fix free nitrogen.

Comparative absorption of salts of barium, strontium, and calcium by living plants, H. Colin and J. de Ruez de Lavison (Rev. Gén. Bot., 22 (1910), No. 261, pp. 337–334).—In a previous publication (E. S. R., 3, p. 328) the authors reported upon the localization of barium salts in the roots of peas grown in cultures which contained small quantities of barium. Subsequent studies have been made of strontium and calcium salts.

While almost no trace of barium was to be found in the stems, strontium occurred in small quantities and calcium abundantly, showing that the salts of the latter two alkaline metals can penetrate the roots of peas and be transferred to the stems and other organs, but not the salts of barium. The results were confirmed with other plants, as beans, lentils, lupines, maize, wheat, hycacinth, etc.

The excretion of mineral and organic substances by roots and water pores of plants, P. Massé (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 8, pp. 452–455; abs. in Rev. Sci. [Paris], 49 (1911). 1, No. 9, pp. 282, 283).—The author shows by his experiments that roots return not only mineral matter but also organic substances to the soil. In a like manner inorganic substances are eliminated through the water pores of the leaves.

The water collected from the leaves was found to contain chlorids, sulphates of lime and magnesia, nitric acid, and ammonia. The elimination of the unused mineral matter by roots and leaves, it is said, determines the composition of the ash of plants, the absolute weight of which will be increased or diminished according to the absorption.

Reduction by roots, O. Schreiner and M. X. Sullivan (Bot. Gaz., 51 (1911), No. 2, pp. 121–130).—A report is given of experiments on the reducing power of seedlings grown in soil or solutions. The experiments were made to determine the power of uninjured growing roots, especially of wheat, to reduce substances, with the purpose of seeing if, like the oxidative power, the reducing power would be found to play a significant part in soil fertility.

Studies were made with wheat seedlings grown in various solutions, showing that they were quickly decolorized, after which experiments were carried on with seedlings placed in starch iodid solution, sulphur, nitrates, sodium selenite, and sodium tellurite to test their reducing power.

The experiments showed conclusively that uninjured roots possess a reducing power which is stronger in young seedlings and diminishes as the seedlings become older. As judged by the quickness with which the deposit of selenium is made on the roots and the intensity of the deposit, the reducing power increases from the time of germination to the sixth or eighth day and then decreases. On the other hand, the oxidizing power of wheat seedlings is said to be less in the young seedlings, increasing with age.

A bibliography is appended.

Some investigations on the action of wind on plant growth, F. Cavara (Bul. Orto Bot. R. Univ. Napoli, 2 (1910), No. 4, pp. 505–512, pl. 1).—The results are given of experiments on the effect of wind on the growth of Iresine herbstii, Colcus hybridus, Aster chinensis, Zinnia violacea, and Sempervivum clusitanum.

It was found that in most instances the main axis of the stem was shortened and thickened, resulting in a closer leaf formation approaching to a rosette type of growth. This was especially noticeable in C. hybridus and A. chinensis.
The author, therefore, concludes that wind is one of the important factors in the development of plant formations or facies.

Plants and tobacco smoke, H. Molisch (Umschau, 15 (1911), No. 13, pp. 259-261, figs. 5).—A report is given of experiments conducted to test the effect of tobacco smoke on plants. Seeds of vetch, beans, peas, and pumpkins were sown and transferred to water cultures, after which they were placed under bell jars, and in one of each series a large amount of tobacco smoke was blown.

After six days the plants were examined. All those seedlings which had been kept in an atmosphere consisting largely of tobacco smoke and respired air were shorter, had thicker stems, and in many instances the plants were negatively geotropic. The injury is attributed to the tobacco smoke, which the author says contains nicotin, pyridin compounds, sulphureted hydrogen, etc.

The results are said to have an important bearing on plant growing in dwellings, restaurants, show windows, etc., where there is a possibility of injury due to illuminating gas, heated air, tobacco smoke, or other deleterious substances.

The comparative toxicity of vegetable volatile oils on plants, H. Coupin (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 9, pp. 529-531).—The author reports upon a series of experiments with wheat seedlings which were confined under bell jars in atmospheres practically saturated with the vapor of a number of essential oils derived from various species of plants.

The great majority of the essential oils were somewhat injurious, about 20 either killing the plants outright or causing their death in a short time, while about an equal number caused injury to the extremity of the leaves. Only about a dozen kinds of essential oils were found to be uninjurious.

The use of saponin in the preparation of insecticides and fungicides, G. Gastine (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 9, pp. 532-534).—Attention is called to the use of the powdered bark of quillaja, Sapindus, and other preparations from a number of species of plants in connection with fungicides and insecticides, the saponin contained in them tending to emulsify the preparations and causing better distribution.

For combating simultaneously aphids, scale insects, and the fungi causing fungagine, the author recommends a solution composed of water 10 liters, Sapindus powder 20 gm., neutral acetate of copper 100 gm., and crude oil or petroleum 200 cc.

Agricultural bacteriology, J. Percival (London, 1910, pp. X+408, figs. 59).—This is a textbook on bacteriology designed for students in agriculture, dairying, and horticulture, and for agriculturists and horticulturists generally who desire to study the causes and methods of control of many natural processes with which they come in contact daily. The work embodies the results of the author's experience in the scientific training of students, and deals with the fundamentals of bacteriology so far as the requirements of the farm and garden are concerned.

A bacteriological museum and bureau for the exchange of bacterial cultures at the American Museum of Natural History, New York, C. E. A. Winslow (Abs. in Science, n. ser., 33 (1911), No. 839, p. 539).—The department of public health at this museum has equipped a laboratory to serve as a central bureau for the preservation and distribution of bacterial cultures of both pathogenic and nonpathogenic organisms and particularly of types of new forms and varieties. The laboratory also plans to keep on file descriptions of bacterial species in print or arranged in the form of the standard card.

The proposed microbiological central station in Berlin, O. Rahn (Abs. in Science, n. ser., 33 (1911), No. 839, p. 539).—A review is given in this paper of efforts put forth in Germany to establish a central station for the investigation, preservation, and distribution of microbiological cultures.
Contributions to the cytology of the bacteria, C. C. Dobell (Quart. Jour. Micros. Sci. [London], n. ser., 56 (1911), No. 223, pp. 395-506, pls. 4, fig. 1).—After a general review of the literature on the cytology of the bacteria, in which the views of each investigator are briefly stated, together with the technique used, the author describes his own methods and gives the sources of his material, descriptions of the forms investigated, and the cytological results obtained from the studies.

The conclusion is reached that all bacteria which have been adequately investigated are, like all other protista, nucleate cells. The form of the nucleus is variable in different bacteria and in different periods of the life cycle of the same species, and may consist of a discreet system of granules (chromidia) of one or more relatively large aggregate masses of nuclear substance, of a system of irregularly branched or bent short strands, rods, or networks, or of a filament of varying configuration, and probably also may exist in the vesicular form characteristic of the nuclei of many plants, animals, and protists.

Nuclei equivalents and nuclei of Azotobacter chroococcum and its spore formation, E. Mencl (Arch. Protistenk., 22 (1911), No. 1, pp. 1-18, pl. 1).—After a general description of the material and methods used in his investigations, the author gives the results of a cytological study on the internal structure and spore formation of Azotobacter, in which a simple form of mitosis, nuclei or their equivalents, sporulation, and involution forms were observed and described.

On the mineral needs of Azotobacter, H. Kaserer (Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 2, pp. 97-123).—This is a more extended discussion of investigations by the author on this subject, including details as to methods used and data obtained in arriving at the results which were summarized in a previous paper (E. S. R., 24, p. 20).

Viability of Pseudomonas radicicola on ash-maltose agar, S. F. Edwards (Abs. in Science, n. ser., 33 (1911), No. 849, pp. 543, 544).—During the latter part of 1906 cultures of P. radicicola were isolated from the nodules of 19 hosts on ash-maltose-agar and then transferred to the same medium in Freudenreich flasks which were kept in a darkened cupboard at laboratory room temperature. In the autumn of 1910 plates were made from these old cultures with the result that in 35 of them the organism was still living. Pot tests in sterile sand, using seeds of alfalfa, red clover, peas, and beans were started, but only the peas were sufficiently developed at the time of writing to examine.

Of 6 noninoculated control plants, 3 showed no nodules, and 3 showed 1, 10, and 12 nodules, respectively, while the 6 inoculated plants showed 18, 33, 20, 25, 64, and 25 nodules, respectively. The work thus far shows that P. radicicola retains its virility as well as its vitality after considerable periods of time in stock cultures under laboratory conditions.

The influence of quartz sand upon microbial cultures, O. Rahn (Abs. in Science, n. ser., 33 (1911), No. 849, p. 544).—The object of this investigation was to study the influence of soils upon micro-organisms. The decomposition of liquid media was compared with that of the same liquid absorbed in quartz sand, and great differences were found. Aerobic processes were greatly increased and anaerobic processes much decreased when the liquid was mixed in sand in such proportions as to allow abundant aeration, but both processes were favored when just enough liquid was added to the sand to keep it entirely submerged.

Biochemical factors in the soil. M. X. Sullivan (Abs. in Science, n. ser., 33 (1911), No. 849, p. 543).—Attention is called to the fact that the soil is not an inert reservoir for plant food, but is the seat of physical, chemical, and
vital activities, the biochemical factors being especially prominent. Numerous bodies which occur in soils arise either in the metabolic activities of microorganisms or are left there after the decomposition of the plant and animal débris, and probably also as a result of root excretion or cell sloughing. Some of these substances are harmful, and others beneficial to crops. Fertilizers tend to modify the physiological functions of the micro-organisms by bringing about suitable conditions for their development, by stimulating or retarding their digestion of inert bodies, and by furthering their enzymatic functions.

**Bacteria of frozen soil,** H. J. **Conn** (*Abst. in Science, u. ser., 33 (1914), No. 849, p. 553*).—The author briefly summarizes the results of investigations on this subject carried on at Ithaca, N. Y., during 1909-10, which showed a remarkable increase in soil bacteria during the winter, the increase being from 7,000,000 per gram in November, 1909, to 23,000,000 in February, 1910, and from 8,000,000 in November, 1910, to 22,000,000 in December, 1910. The quantitative results have been previously reported (E. S. R., 24, p. 529), while the qualitative work, including the study of some 300 cultures, is here discussed.

It was found that certain organisms were present throughout the year, while others appeared only at times and showed a tendency to reappear at the same seasons another year, fall and winter showing the greatest diversity of types. Four groups of bacteria were studied, as follows: (1) Higher filamentous bacteria (Actinomycetes); (2) rapid liquefiers producing spores, mostly of the *Bacillus subtilis* group; (3) rapid liquefiers without spores, all but one being *Pseudomonas* forms; (4) slow growers without spores, producing punctiform colonies, partly liquefiers and partly nonliquefiers. This last group is the one containing the bacteria which increase the most noticeably in the winter.

**On methods of measuring the bacterial activity of cultivated soils,** R. **Perotti** (*Atti R. Accad. Lineei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 29 (1911), I, No. 4, pp. 266-274, fig. 1*).—The author briefly reviews the methods of prominent investigators, especially Remy's, for determining ammonification, nitrification, denitrification, and nitrogen fixation in different soils, and concludes that Remy's methods as used by Barthel (E. S. R., 21, p. 528) for the study of soil bacteriology are probably the best.

Attention is called to the results obtained in measuring ammonification, nitrification, and denitrification in certain Italian soils (E. S. R., 24, p. 717), in which there was a marked difference between ammonification and nitrification produced by certain of these soils during the winter and summer seasons, being much greater during the month of February than in July. These experiments also showed a greater degree of nitrification for soils having 10.5 per cent of organic matter than soils containing only 8.8 per cent.

**Bacteriological studies of the soils of the Truckee-Carson irrigation project** [Fallon, Nev.], K. F. **Kellerman** and E. R. **Allen** (*U. S. Dept. Agr., Bur. Plant Indus. Bul. 211, pp. 36, figs. 20*).—The results are given of experiments on the nitrifying and ammonifying power of soils at different depths, on the nitrification of samples in solution, on the relation of chlorids and sulphates to nitrification, and on denitrification. The relative number of bacteria in different soils were estimated, and detailed studies of soils typical of extensive areas reported. All studies were made of a 3-foot zone, keeping sepa-
rate the samples of soils from different depths, and the results shown by a series of diagrams.

It was found that nitrifying, denitrifying, and ammonifying bacteria were well distributed and universally present in the soils of the Truckee-Carson irrigation project, and became physiologically active when favorable conditions for their development occurred. The lack of proper decay and humification of organic matter in many of the unproductive soils is due either to unfavorable bacterial conditions produced by certain physiological and chemical factors or to an unusual bacterial flora. The nitrifying bacteria in the soils of Fallon, Nev., are active at greater depths than in eastern soils, and seem to be unusually virile in solutions, although the data on these points are not conclusive.

In general, the conditions favor nitrification, which frequently becomes intense, while those favoring denitrification are rare.

Upon assimilation of atmospheric nitrogen by fungi, L. H. Pennington (Bul. Torrey Bot. Club, 38 (1911), No. 3, pp. 135-139).—The author gives the results of experiments on the fixation of nitrogen by Penicillium, Aspergillus niger, Alternaria, and 3 species of Fusarium, in which no evidence of any fixation of nitrogen by these plants was found. The author believes that some of the positive results obtained by certain investigators on the fixation of nitrogen by fungi are due to errors of observation and technique, or to the use of different species of fungi under the same name by different investigators, as it is very possible that some strains of fungi are able to fix nitrogen, while other very similar strains or varieties do not have this ability.

Experiments with cyanamid-decomposing bacteria, H. Kappen (Centbl. Bakt. [etc.], 2. Abt., 24 (1909), No. 13-15, pp. 382-404; abs. in Bot. Centbl., 114 (1910), No. 43, pp. 532, 533).—The author claims to have found 4 bacteria, which in lime nitrogen and cyanamid solutions are able to decompose the cyanamid.

It is further stated that neither carbon dioxide nor organic acids are able to change the cyanamid in culture solutions and in the soil. The favorable action of grape sugar on the decomposition of the cyanamids is not due to the influence of the decomposition products of this kind of sugar, but is attributed to a physiological action on the bacteria.

It was also found that 2 fungi, Cladosporium and Penicillium brevicaulc, played a part in the decomposition of the cyanamid.

The clogging of drain tile by roots, G. E. Stone (Torreyca, 11 (1911), No. 3, pp. 51-55, fig. 1).—An account is given of the clogging of a 12-inch drain tile by the roots of a pear tree, a single root having penetrated the tile. From its cross section the root was apparently 5 years old. The tile was clogged to a distance of 61 feet. The principal roots removed were measured and the others estimated, from which it appeared that there was a total length of roots amounting to 8,498 feet in the section of tile removed.

The mycoplasn theory and metachromatic corpuscles, J. Beauverie (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 10, pp. 612-615).—In a study of cross sections of young rust sorl on wheat leaves, the author found many nucleus-like bodies not only in the fungus hyphae, but also in the neighboring cells of the host. These bodies when stained with certain anilin dyes changed from blue to violet, and are called metachromatic bodies. The author, therefore, claims that the nuclei of the so-called mycoplasm of Eriksson are nothing more than these metachromatic bodies.

Variation of fungi due to environment, F. L. Stevens and J. G. Hall (North Carolina Sta. Rpt. 1909, pp. 47-71, figs. 37).—Previously noted from other sources (E. S. R., 21, pp. 33, 626),
A quantitative study of variation, natural and induced, in pure lines of Silene noctiflora, E. P. Humbert (Ztschr. Induktive Abstam. u. Vererbungslehre, 4 (1911), No. 3-4, pp. 161-226, figs. 11).—A study is reported of three generations of a pure line of S. noctiflora, about 7,500 plants being measured for height, width, and number of branches and seed pods per plant. The investigations included studies of the influence of chemical injections on variation, effectiveness of selection in pure lines, bud variation, and the influence of food supply on variation.

So far as the author's experiments go, it appears that the injection of chemical stimulants in the developing ovary did not produce mutations, although such injections did produce in many instances a marked increase in the variability of the species.

In his study of the effectiveness of the selection in pure lines, little evidence was found of the inheritance of the characters of height, number of branches, or number of seed pods. Some variation was noted, but not enough to warrant the description of mutants.

In considering bud variation, in the cases studied the buds were found to vary almost as much on single plants as they did on different individuals.

In studying the influence of food supply on variation it was found that good soil gave less variability and a greater correlation of characters than did poor soil. Other factors, as moisture, temperature, and physical condition of the soil, probably had some influence, but under the conditions of the experiments an increase in food supply decreased rather than increased variability in S. noctiflora.

On inheritance of a mutation in the common foxglove, Edith R. Saunders (New Phytol., 10 (1911), No. 1-2, pp. 47-63, pl. 1, figs. 12).—A description is given of inheritance observed in a form of the foxglove to which the name Digitalis purpurea heptandra is given.

This form of the plant is characterized by the splitting and staminody of the corolla, and these characteristic features appeared to be transmitted by heptandrous plants to all their offspring. The degree in which these peculiarities were exhibited varied not only among the individuals of a pure-bred family, but also among the flowers of single individuals. There is said to be some indication that the degree of heptandry exhibited may be influenced by external conditions, among which, variations in amount of light and moisture are probably to be considered. D. purpurea heptandra was found to behave in respect to the type as recessive to dominant.

Seeds and plants imported during the period from January 1 to March 31, 1910.—Inventory No. 22 (U. S. Dept. Agr., Bur. Plant Indus. Bul. 207, pp. 100).—This inventory is a report on 1,010 introductions by the Office of Foreign Seed and Plant Introduction during the period indicated. In addition to a considerable amount of material received from miscellaneous collectors, it also lists a large number of species secured from the Caucasus by F. N. Meyer, agricultural explorer.

Seeds and plants imported during the period from April 1 to June 30, 1910.—Inventory No. 23 (U. S. Dept. Agr., Bur. Plant Indus. Bul. 208, pp. 88).—This inventory contains accounts of material collected by F. N. Meyer in the Caucasus, together with a large number of plants obtained through various sources, a total of 844 introductions being listed.
FIELD CROPS.

Experimental work [with field crops] (Oregon Agr. Col. Bul., I, ser., 1911, No. 48, pp. 5-27, 35, 36, 38-40, figs. 16).—Work at the eastern Oregon substation is here reported.

In a test of 6 varieties Sixty Day and Shade land Challenge oats yielded 41.68 and 38.40 bushels per acre, respectively. Among 8 varieties tested during the period 1907-1909 the 3-year average yields of Improved American and Silver Mine were 83.85 and 77.52 bushels per acre, respectively.

In a test of 12 barley varieties Beardless and Getekoun produced the highest yields of 56.45 and 41.47 bushels per acre, respectively. In a much more extensive test it was observed that the dark-colored barleys were the heaviest yielders, and "that 30-8, 30-18, and 30-24 are probably the most promising." The comparative yields of 50 of the station's new hybrid barleys are graphically indicated.

Alaska and durum wheat under field conditions yielded 16.86 and 14.94 bushels per acre, respectively. The station has produced a hybrid which unites the high yielding qualities of Fortyfold and the nonshattering qualities of Little Club besides giving the milling test desired.

In a field test of 5 varieties of field peas White Marrowfat produced the highest yield of 13.39 bushels per acre and was regarded as a promising variety. In another test of 55 varieties, conducted in cooperation with this department, Brown B produced the highest yield.

The Half Sugar mangel yielded 25.90 tons of roots and 5.59 tons of tops per acre, while clover yielded nearly 2 tons of hay, 228.94 pounds of seed, and over 1 ½ tons of straw per acre, with a total estimated value of $60.13 per acre. Dwarf Essex rape proved less hardy than kale, and the latter yielded 42 tons of summer forage per acre in a field test. A field test of seed flax produced an unsatisfactory yield of 11.92 bushels per acre.

In attempts to control mustard in oats the field sprayed with iron sulphate yielded 38 bushels per acre as compared with 42.86 bushels on the untreated field, and 42.25 bushels on a field cultivated by a weeder, which thoroughly stirred the surface soil without apparent injury to the grain. The yield of mustard seed per acre was 12.65, 26.05, and 22.11 bushels per acre, respectively, after the 3 treatments.

In a test of 20 varieties of potatoes Nohoot produced the highest yield of 252.73 bushels per acre. In a test of 10 varieties Salina Burbank potato produced the maximum yield of 258.8 bushels per acre. Three varieties of field corn failed to mature ears, but Yellow Dent matured about a dozen ears.

Summary of five years' results of cooperative tests of varieties of corn, wheat, oats, soy beans, and cowpeas, 1906-1910, A. T. Wiancko and C. O. Cromer (Indiana Sta. Bul. 149, pp. 3-23, fig. 1).—This bulletin summarizes the results of the variety tests previously noted (E. S. R., 22, p. 725), and reports the results secured in 1910, the yields being reported by sections of the State numbered as in former years. Brief descriptions are given of the varieties tested for two or more years, and the summaries include the results obtained in 3,731 tests covering various seasons and every soil type represented in the State.

The table following presents the highest yields secured in each of the geographical sections.
Yields of the most productive varieties of field crops in 1910 in tests in various sections of Indiana.

Report on the Partabgarh Agricultural Station for the year ending June 30, 1910, S. M. Hadz (Rpt. Partabgarh Agr. Sta. United Prov. Agricra and Oudh, 1910, pp. 8).—Meteorological data and analyses of the station’s soil and subsols are followed by reports of variety and other tests of rice, corn, sugar cane, and wheat.

Progress of grain investigations, C. Willis and M. Champlin (South Dakota Sta. Bul. 124, pp. 20–55, chart 1).—A progress report of cooperative experiments conducted by the South Dakota Station and this Department at the Highmore, Eureka, and Cottonwood substations. Seasonal conditions and the methods pursued are stated and the Eureka and Cottonwood substations briefly described. Tables report the yields of common wheat, durum wheat, emmer, oats, barley, millet, and grain sorghums for the year 1909, the comparative results of ordinary and improved methods of growing grains in 1910, and the average yields secured in five-year variety tests. The improved methods used consisted in carefully grading pure seed, planting it in rows in 1909, grading the seed thus obtained, and planting the best in 1–100 acre plots in 1910 on land that had been in cultivated alfalfa rows during 1908 and 1909.

The author states that recent analyses “show that northwestern Velvet Chaff has improved as regards quality of gluten and percentage of patent flour so that the discrepancy in milling value may not affect the market price much in the future.” The Beardless Fife wheats graded as well as Blue Stem and ripened two or three days earlier. In a variety test of 14 wheats Manchuria No. 2492 produced the highest yield of 21.2 bushels per acre. It was also the earliest variety in the test. Of durum wheats the Kubanka types appeared best suited to central South Dakota conditions.

Because of the variable seasons an early and a late variety of oats, Sixty Day or Kherson and Swedish Select, are recommended to South Dakota farmers.

In a test of 14 Foxtail and Proso millets, Kursk No. 78, a variety introduced from Russia, produced the heaviest yield of forage, but the common variety seeded more heavily. Milo maize, Kafir corn, and the duras will not mature seed with certainty under South Dakota conditions, but selections are being made in the hope of securing strains that will mature during the short seasons. The kowliangs matured seed of excellent quality in 114 to 115 days in 1909 and 1910. New breaking, brome grass sod, and corn ground proved successful as preparations for flax, but after fall-plowed wheat this crop was a failure because of flax wilt.
In the five-year variety tests Kubanka wheat Nos. 1516 and 1354 yielded 22.7 and 22.5 bushels per acre, respectively, as compared with 14.9 bushels each Bearded Red Fife and Minnesota No. 51 Blue Stem. The five-year average yields of Swedish Select No. 134 and Kherson No. 539 were 35.4 and 33.9 bushels per acre in a test of 14 oat varieties. Hanachen No. 531 and Bohemian No. 27 produced five-year average yields of 28.4 and 27.5 bushels per acre, respectively, in a test of 10 barley varieties.

Lucern, J. E. O'Grady (Dept. Agr. N. S. Wales, Farmers' Bul, 37, pp. 118, pl. 1, figs. 48).—This bulletin is a compilation of articles dealing with the production and utilization of crops of lucern or alfalfa.

Some facts concerning those characters of the corn plant associated with yield and factors which influence them, C. B. Williams and W. C. Etheridge (North Carolina Sta. Rpt. 1909, pp. 41-50).—Six years' variety tests indicate "that the prolificity of stalks in ears should be given prime consideration in selecting corn." Sanders Improved, a fairly prolific variety, produced a five-year average yield 6.8 bushels per acre higher than did Holt Strawberry, a good one-eared variety. Biggs Seven-eared, another prolific variety, produced a three-year average yield 4.4 bushels higher than that of Holt Strawberry.

Studies of shelling percentage indicate that a given variety may have a seasonal variation of 2 to 4 per cent or more, but that the best yielding varieties average from 80 to 87 per cent of grain.

The author presents in detail data from which he draws conclusions on the effect of different rates of planting and fertilizing upon yield, size of ears, height of ears and stalks, maturity, stand, production of suckers, and barrenness. Under poor fertilization there was practically no difference in yield between a spacing of 20 and 30 inches of the hills in the rows, but increasing the productivity of the soil by liberal fertilization "was accompanied by materially increased yields, over 30-inch spacing, by thinning the stalks to 20 inches."

On highly manured plats the stalks 30 inches apart produced the largest and longest ears, but gave lower yields than the 20-inch spacing. High fertilization and increased distance between hills increased the length and circumference of the ears of from two-thirds to three-fourths of the varieties tested. When plant food was limited in quantity the increase from 20 to 30 inches in distance between stalks in 4-foot rows was followed by the production of taller stalks and of ears attached farther from the ground, whereas the reverse followed on the same soil fairly well fertilized. An increase in either soil fertility or distance between hills resulted in a larger number of ears per stalk and a marked increase in the yield of shelled corn per bearing stalk.

Variation in the rate of planting produced no apparent difference in the extent of growth of the plants up to the time of tasseling and silking, but the closer spacing appeared to delay maturity about one day. The higher fertilization was followed by the production of suckers on 9.48 and 6.13 per cent, respectively, of the stalks planted 30 and 20 inches apart in the rows, while on poorly fertilized plats the percentages were 6.15 and 2.87, respectively. Barrenness was apparently decreased by either increasing the distance between hills or heavier fertilization.

Corn production, M. V. Calvin (Georgia Sta. Bul, 93, pp. 147-153, fig. 1).—During 1907, 1908, and 1909 Marlboro Prolific and Stone Flint were among the three varieties producing the highest yields in variety tests. In 1910 Wanamaker Marlboro, Sanders Improved, and Batt 4-Ear produced the highest
yields, 36.15, 36, and 35.88 bushels per acre, respectively. The 15 varieties tested averaged 31.74 bushels per acre. A measured acre given special attention yielded 80 bushels of shelled corn, 800 pounds pulled fodder, and 1,320 pounds topped plants.

In a nitrogen test a basic formula was supplemented by different fertilizers in quantities that furnished the same amount of nitrogen each. The cotton meal, nitrate of soda, and sulphate of ammonia plats yielded 42.1, 43.04, and 44.46 bushels of shelled corn per acre, respectively, as compared with 37.22 bushels yielded by the no-fertilizer plats. On land previously sown to oats, then to cowpeas, applications of the same basic formula were followed by yields of 38.36 and 33.79 bushels of shelled corn per acre, respectively, when supplemented by cotton meal and tankage. A half cotton meal and half tankage addition to the basic formula yielded 40.57 bushels per acre.

Seed from the butts, tips, and middles of the ears yielded 35.22, 36.7, and 32.92 bushels per acre, respectively. Two stalks per hill yielded 56.16 bushels per acre as compared with 42.21 bushels when only one stalk was planted per hill. The Williamson method produced in a three-year test an average of 32.62 bushels as compared with 34.18 bushels obtained by the ordinary method. The cultural and other methods used in each of these experiments are stated in full.

Cotton, É. de WildeMAN et AL. (Rev. Écon. Internat., 8 (1911), II, No. 1, pp. 215).—A series of articles by different authors on the following subjects: The uses of the cotton plant and its improvement, the culture of cotton in the various countries of the world, the world's production and consumption of cotton, the cotton industry and the periodical crises of overproduction, the International Federation of Cotton Spinner's and Manufacturer's Associations, financial affairs with reference to the industry, the history of inventions used in cotton culture and manufacture, and the history of cotton transportation.

Cotton production, M. V. Calvin (Georgia Sta. Bul. 94, pp. 153-164).—In a test of 33 cotton varieties averaging 1,804 pounds of seed cotton per acre McElhenny Cleveland and J. R. Cleveland Improved produced the highest yields, 2,256 and 2,206 pounds per acre.

In a nitrogen test cotton meal, nitrate of soda, and sulphate of ammonia plats yielded 1,246.18, 1,230.72, and 1,297.94 pounds of seed cotton per acre, respectively, as compared with 963.04 pounds on the no-fertilizer plats. This is a repetition of an experiment conducted the previous year (E. S. R., 22, p. 035).

Applications of 33 pounds of muriate of potash and 132 pounds of kainit in mixtures otherwise identical were followed by yields of 1,671.29 and 1,603.76 pounds of seed cotton per acre as compared with 1,320.68 pounds on the no-fertilizer plats. In another test applications of cotton meal and tankage were followed by yields of 1,824.47 and 1,873.04 pounds of seed cotton per acre as compared with 1,867.32 pounds after a mixture of the two materials, and 1,647.88 pounds on the nonfertilized plats.

The cultural and other methods used in each of these experiments are stated in full.

Effect of different fertilizing materials upon the maturity of cotton, C. B. Williams (North Carolina Sta. Rpt. 1909, pp. 37-40).—In about 30 tests of fertilizing materials combined in different proportions and applied in different quantities a hastening of maturity was invariably observed, and in most cases the greater the yield the greater was the percentage of the total crop which was obtained at the first two pickings. At these first two pickings the sandy and
sandy loam soils yielded higher percentages of their total cotton crop than the red clay soils, whether fertilized or unfertilized.

On sandy and sandy loam soils heavy and medium heavy phosphoric acid fertilization with normal amounts of other plant foods produced the largest percentages of the seed cotton open at the first picking. Normal fertilization yielded a larger percentage of the cotton open at the first picking than high nitrogen applications on sandy and red clay soils, while potash applications yielded still lower percentages of the total yield open at the first picking on all soils studied than did the high nitrogen applications. When used with commercial fertilizers air-slaked lime increased the tendency to cause early maturity, but when used alone the lime did not hasten maturity.

Cultivation of broach cotton in Dharwar, M. L. Kulkarni (Dept. Agr. Bombay Bul. 33, 1909, pp. 8).—In a comparative test Broach excelled Kumptha cotton by 100 pounds per acre in yield, and 8 per cent in lint percentage. Its cost of cultivation was nearly one and one-third times as great, but the value per acre of the yield was over one and one-third times as great.

Hindi cotton in Egypt, O. F. Cook (U. S. Dept. Agr., Bur. Plant Indus. Bul. 210, pp. 58, pls. 6).—This paper presents observations on the results of the mixture of inferior Hindi cotton with Egyptian cotton, made during a visit to the cotton-growing districts of Egypt. It deals with the importance of uniformity in Egyptian cotton, the character of Hindi cotton plants and their lint and seed, and the characters of hybrids of Hindi and Egyptian cottons and their relationships.

The claim that Hindi cotton is all removed from the field at time of thinning was disproved by the fact that obvious hybrid forms and plants of the Hindi type remained in the fields, sometimes constituting more than 10 per cent of the total number of plants. Although the careful hand grading and sorting by cheap labor, which brings about uniformity in the Egyptian-grown cotton, is not possible in the United States, the author believes that with reasonable care in maintaining uniformity of type in the field it is not apparent "that the American-grown Egyptian cotton is likely to suffer any commercial disadvantage on the ground of lack of uniformity in comparison with the Egyptian crop."

Proceedings of the cotton-culture commission of the colonial agricultural committee (Verhandl. Kolon. Wirtschaftl. Kom., 1910, No. 2, pp. 63, pl. i).—This report contains a collection of papers by different authors treating of the cotton-culture enterprises undertaken in German East Africa.

The possibilities of growing cotton in Togo, Uganda, and various sections in German East Africa are discussed, together with the advisability of establishing cotton gins and cottonseed-oil mills in certain localities. The possibilities of growing and exploiting *Eriodendron anfractus*, as well as species of Calotropsis, plants from which fiber is obtained, are briefly noted.

Cotton growing in Ceylon (Circs. and Agr. Jour. Roy. Bot. Gard. Ceylon, 5 (1910), No. 14, pp. 181-200).—This circular points out the prospects for the development of the cotton-growing industry under existing conditions in Ceylon, and the possible developments which might follow from either the introduction of foreign capital on a large scale or a vigorous attempt on the part of the Government to extend the industry. One of the principal hindrances to the investment of capital in this industry is the intermittent nature of the employment afforded for labor of cotton cultivation, but it is believed that the cultivation of cotton would be an industry well suited for the small native capitalists, who can not afford to wait long for a return.

Fibers used in textile and allied industries, C. A. Mitchell and R. M. Prideaux (London, 1910, pp. XII+196+32. figs. 66).—Microscopical descriptions and chemical tests are given, as well as general descriptive material
regarding wool, silk, cotton, and other fibers in this handbook, which, as the authors state, deals with the principal fibers used in "what for want of a better term may be called the 'isolated' condition," that is, "fibers used in a more or less dissociated condition in spinning, weaving, cordage, brush making, and upholstery."

Report of field trials with varieties of oats, T. Milburn and A. W. Patten (County Council Lancaster, Ed. Com., Agr. Dept., Farmers' Bul. 18, pp. 7).—In a test of 6 oat varieties on each of 4 farms in 1909 Wide Awake and Banner produced the highest grain yields of 63 and 63½ bushels per acre, respectively, while in 1910 the highest average yields on 3 farms were 54 and 53 bushels per acre, secured from Banner and Beseler Prolific, respectively. At 3 of the 4 centers in 1909 Irish seed gave higher grain yields than English seed, but the straw yields were approximately equal. In a milling test Banner gave 67.7 per cent of meal to grain and the Irish and English Waverly gave 63.3 and 58.8 per cent, respectively. Varieties of the grain producing type gave the higher yield percentages and the larger amounts of meal per acre.

Report on the experiments conducted by the German Potato-Culture Station in 1910, C. von Eckenberg (Zyschr. Spiritusindus., 1911, Supp., pp. 3-60).—The results of experiments with 140 varieties of potatoes are tabulated in detail and the performance record of each variety is described at length. These varieties were tested on experiment fields located in different sections of the country. Attention is given to yield of tubers, starch content, resistance to disease, and value for different purposes.

The highest yields of tubers were secured from the varieties Vater Rhein and Jubelkartoffel, and the highest yields of starch from Lucy and Vater Rhein. The varieties Schladen Ruhm and Agraria ranked highest in starch content.

Report on experiments with potatoes conducted in 1910 by F. Heine at Kloster Hadmersleben, W. Oetken (Zyschr. Spiritusindus., 1911, Supp., pp. 65-75).—The results for the year are reported upon at some length and the annual results secured since 1877 are summarized.

During this entire period an average yield of 24,206 kilograms per hectare of tubers, an average starch content of 18.41 per cent, and an average starch yield per hectare of 4,456 kilograms were secured. A total of 1,388 varieties was tested on 4,700 plats, exclusive of check plats. In the discussion of the different varieties special reference is made to yielding capacity, starch content, period of maturity, and the value for culinary, feeding, and industrial purposes.

Varieties of potatoes utilized for manufacturing starch, E. Parow (Zyschr. Spiritusindus., 33 (1910). No. 37, p. 447; abs. in Chem. Ztg., 31 (1910), No. 133, Repert., p. 510).—This article contains reports from 97 starch factories in relation to the comparative starch yields from various kinds of potatoes.

Analyses of potatoes grown in 1909 and 1910, J. F. Hoffmann (Zyschr. Spiritusindus., 1911, Supp., pp. 61-64).—The results of experiments covering two years, here reported in tabular form and discussed, point out that no one variety was markedly superior to any other grown in the test. The respiratory experiments carried on in this connection showed that Up-to-date and Barbarossa were distinguished by good keeping quality.

Literature on the races of rice in India (Agr. Ledger, 1910, No. 1 (Veg. Prod. Ser., No. 113), pp. 334).—This is an index to the literature on the races of rice in India.

The chemical structure and its influence on the sugar content of Beta vulgaris, O. Claassen (Chem. Ztg., 34 (1910), No. 149, pp. 1329, 1330).—A study was made of beets characterized by an exceptionally heavy root formation and of the appearance in the root of concentric, dark, or dark blue rings containing cell sap bitter to the taste. The roots of these beets were also malformed in other ways but mainly through many divisions.

The results of chemical analyses showed that the beets were exceptionally low in sugar and very high in nonsugars, but in moisture content there were no great differences as compared with normal beets. It was further found that as regards the mineral constituents the normal and the abnormal beets differed materially only in the content of potash, silicic acid, and chlorin. As it has been observed that when the calcium content is reduced the potash content is increased, the author believes that the high moisture requirements of the beet cause a heavy growth of secondary roots, and that with the water-soluble substances, which are the first to enter the beet, potash salts, and in part chlorids of potash, are taken up. As this increases the chlorin content the possibility for the lime to enter into combination in the beet is reduced. This explanation is given for the low sugar content of the abnormal beet which would result from the formation of calcium saccharids and saccharates, and from the particular form of the potash salts.

The influence of light on the composition of the sugar beet, F. Strohmer, H. Briem, and O. Fallada (Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 40 (1911), No. 1, pp. 11–28).—The results are given of experiments with sugar beets in which the beets were so planted that part of them were shaded in the morning and part in the afternoon by trees.

It was found that the foliage growth of the shaded beets was greatly increased and at the expense of the root development. The shaded beets produced, in comparison with unshaded ones otherwise grown under like conditions, very small quantities of dry matter in the roots, and this loss of dry matter for the most part occurred in the sugar content, while on the other hand, the nitrogen content of the roots of the shaded beets was the higher. The leaves of the shaded beets contained appreciably larger quantities of oxalic acid than similar unshaded plants, and the ash content of both roots and leaves was increased by shading. Especially was the movement of the chlorids accelerated.

The authors, therefore, conclude that the shading of sugar beets is injurious to their development for sugar making, and that meteorological observations for the sugar-beet grower ought to include the measuring of the light intensity of the locality under consideration.

A bibliography is appended.

Report of an experiment on the manuring of swedes at several centers in the county, during 1907 and 1908, E. Porter and R. C. Gaut (County Council, Lancaster, Ed. Com., Agr. Dept., Farmers' Bul. 16, pp. 12).—This bulletin reports the results of fertilizer tests of swedes at four centers in 1907 and at six in 1908. In each instance the plats were fertilized with 10 tons of farm-yard manure per acre.

The average calculated profits at the ten centers indicate that the application of 10 tons more of manure resulted in a loss of 7 shillings 5 pence and that the highest gain after deducting the cost of the fertilizer followed an application of 1½ hundredweight of nitrate of soda, 4 hundredweight of superphosphate, complete fertilizers gave larger results than the incomplete mixtures.
Tobacco culture in Wisconsin, J. Johnson (Wisconsin Sta. Bul. 296, pp. 3-30, figs. 6).—This bulletin gives directions for tobacco production in Wisconsin and 3 hundredweight of kainit in addition to the 10 tons of manure. Three topics especially dealt with are the soil, fertilizer, and rotation requirements of tobacco, preparing the plant bed, growing and curing the crop, and the selection of varieties adapted to Wisconsin conditions.

Conference of wheat growers, with special reference to dry farming, J. Perry (Dept. Agr. N. S. Wales, Farmers' Bul. 42, pp. 226, pl. 2, figs. 57).—This presents a series of papers dealing with the growing and marketing of wheat, including a discussion of the special problems of growing the crop under dry-farming conditions.

The adulteration and misbranding of the seeds of alfalfa, red clover, Kentucky blue grass, orchard grass, and redtop, W. A. Taylor (U. S. Dept. Agr., Office Sec. Circ. 35, pp. 6).—This circular reports that of 1,214 samples of seed examined, 204 samples were found to be adulterated or misbranded, these being presented in tables, with the names and addresses of the dealers offering them for sale.

Of 317 samples obtained as orchard grass, 12 were adulterated with the seed of meadow fescue or rye grass. Of 371 samples obtained as Kentucky blue grass, 16 were wholly or in part Canada blue-grass seed. Of 523 samples offered as redtop without mention of timothy seed, 176 were found to contain timothy seed.

Orange hawkweed or paint brush, P. J. White (New York Cornell Sta. Circ. 9, pp. 10-12, fig. 1).—A discussion of the orange hawkweed or paintbrush as a weed is followed by suggestions looking toward its control by salting, cultivation, or manuring.

Fertilizer experiments with small fruits, vegetables, and flowers, Heine (Ber. K. Gärt. Lehranst. Dahlem, 1908-9, pp. 195-204, fig. 1).—The results for 1908-9 are given of tests of various organic and inorganic fertilizers.

Pot culture experiments with a number of flowers indicate that lime nitrogen may be substituted for other nitrogenous fertilizers, provided it is mixed with the soil some two weeks before it is needed and provided basic slag is not used in conjunction with it. The author is of the opinion that the high lime content in the lime nitrogen may render the water-soluble phosphoric acid insoluble. Although lime nitrogen generally gave good results, it did not prove as lasting as ammonium sulphate when used with begonias and petunias.

[Report on fruits, vegetables, and ornamentals] (Oreg. Agr. Col. Bul., 1. ser., 1911, No. 48, pp. 31-34, 36-38, 40-52, 58-68, pls. 13).—Brief data and notes are given on the different varieties of vegetables, fruits, and ornamentals tested at the substation.

The iron-containing vegetables, Kochs (Ber. K. Gärt. Lehranst. Dahlem, 1908-9, pp. 146-158, figs. 9).—The results of experiments on the assimilation of various iron compounds by spinach, rampion, lettuce, sorrel, and beets are reported. The work thus far indicates that the iron content of these vegetables can be increased by fertilizing with various iron compounds. The practical value of these additions and methods of application are yet to be determined.

Cauliflower, F. F. Hasbrouck (Pure Products, 7 (1911), No. 3, pp. 132, 133).—This article deals with the selection of the seed, and the growing, storing, and pickling of cauliflower.

Fruit culture along the middle and lower course of the Volga, V. V. Pashkevich (Ezheg. Dept. Zeml. [Russia], 30 (1909), pp. 400-425, pls. 14,
fig. 1).—The climatic conditions of the above region are described, together with
the varieties of apples, cherries, and plums grown there and the local methods
of culture.

Community fruit growing in Offenburg, Baden, R. Fritzscbe (Deut.
Obstbau Ztg., 1910, No. 10, pp. 171-174).—A descriptive account of community
orcharding in Offenburg, including statistics of yields and revenues, is given.

[Resistance of peach buds and blossoms to frost], F. Garcia (New Mexico
Sta. Rpt., 1910, pp. 17-18).—The investigations reported indicate that peach buds
and blossoms seem to stand a lower temperature in New Mexico than in many
other parts of the United States. The greatest damage is done about the time
the young peach sheds its calyx when the fruit is the size of a pea. The buds
and blossoms withstood a temperature March 27 of 20° F. fairly well. A heavy
frost on the morning of April 17, lasting for 2 hours and during which the tempera-
ture dropped to 24°, resulted in serious injury to the crop.

207, pp. 3-34, figs. 14).—This bulletin treats of those practices of orchard man-
agement which seem best suited to Wisconsin conditions. Consideration is
given to the soil management of bearing orchards and young orchards, fertil-
ization, pruning, and spraying.

An appendix contains general spraying directions.

A practical treatise on banana culture, J. Garcia Salas (La Planta del
Banano o Platano. Mexico: Govt., 1910, pp. 80, pls. 13).—Directions are given
for growing bananas, including suggestions for improving methods of culture
commonly employed in banana-producing countries. The banana is discussed
relative to its botany, uses, species, and varieties, climate, and soils, diseases,
and other enemies, propagation, planting operations, cultivation, fertilizers,
pruning, renewing, drainage, irrigation, harvesting, yields, regions of cultivation,
import countries, and associated crops.

Lemon growing in Sicily, H. de Soto (Daily Cons, and Trade Rpts. [U. S.],
17 (1911), No. 118, pp. 794-795).—The substance is here given of a report pre-
pared by N. Marasa, an expert Italian pomologist, relative to the actual cost
of growing lemons in Italy and the average cost of preparing and packing
lemons for export to the United States. According to the statistics given the net
profit from an acre of lemons in Sicily is about $48.50. The total cost of land-
ing a box of lemons of first quality at New York City was determined as $2.05.

6 (1908), No. 3, pp. 79, 80; abs. in Ztschr. Untersuch. Nahr. u. Genussmtrl., 21
(1911), No. 3, p. 266).—Refrigeration does not inhibit the ripening process
golong on in the interior of the fruit. Investigations by the author in regard to
the most favorable time and temperature indicated these to be for peaches two
months at 0° to 1.1° C., for oranges three months at 1.1°, for lemons four months
at 3.3°, for grape three months at -0.05° to +2.2°, and for ripe tomatoes from
one to two months at 5.5°.

Shade trees in towns and cities, W. Solotaroff (New York and London,
1911, pp. XVIII+287, pls. 9, figs. 250).—A treatise on shade trees dealing
with their selection, planting, and care as applied to the art of street decora-
tion; their diseases and remedies; and their municipal control and supervision.

The subject matter is the result of a study of shade trees in a great many
towns and cities, together with experience gained in the administration of the work
of the East Orange Shade Tree Commission.

Rock and alpine gardening, H. Hemsley (London [1910], 2, ed., pp. 92,
pl. 1, figs. 25).—A treatise on the development of rock, alpine, and water
gardens, including lists of suitable plants with hints on their cultivation.
The practical flower garden, HELENA R. ELY (New York and London, 1911, pp. XIII+304, pls. 32, figs. 38).—A popular work on floriculture, including a discussion of color arrangement of flowers, the raising of flowers and trees from seed, fertilizers and plant remedies, the treatment of terraces, and the wild garden.

FORESTRY.

Forest management, H. MARTIN (Die Forsteinrichtung. Berlin, 1910, 3. ed., rev., pp. XV+281, pls. 11, figs. 4).—A treatise on forest management intended for both instruction and practice. The work is divided into five parts treating in detail of the preliminary work for the laying out of working plans, the economic principles for the preparation of working plans, the laying out of working plans, their control and execution, and methods of forest management. In connection with the last-named subject consideration is given to the methods employed in different countries of Europe.

The extension of the regeneration area, L. A. HAUCH (Centbl. Gesam. Forstw., 37 (1911), No. 4, pp. 147-161, figs. 3).—An exposition on this subject, with particular reference to the proper maintenance and arrangement of older stands in the same forest area for the protection and best development of the regeneration tracts.

Investigations on the leafing-out and other behavior of shade- and light-grown beeches and some other hard woods, A. ENGLER (Mitt. Schweiz. Centralanst. Forstl. Versuchsw., 10 (1911), No. 2, pp. 107-188, pls. 6).—This comprises the results of observations and experiments covering a number of years relative to the influence of light and shade on the development of beech and other hard-wood trees.

The subject matter is discussed under the following general headings: Observations on the leaf development in woods, the growth relations of beeches planted in light and in shade including experiments with forest trees and with cultivated seedlings, pot experiments with light and shade grown beeches, bud development in light and in shade, the influence of weather upon the leafing-out process, and a summary of the results and conclusions.

An appendix contains temperature, sun, and rainfall records for the months of April and May at the Adlisberg station for the period 1900 to 1910, during which the investigations were conducted.

Purple basket willow, C. D. MELL (Amer. Forestry, 17 (1911), No. 5, pp. 286-287, pls. 2).—This paper contains information relative to the commercial value and distinguishing characteristics of the purple willow (Salix purpurea) and its most important varieties and hybrids commonly planted for the production of rods used in making furniture and basket ware.

An artificial method of forcing basket willows (Sci. Amer. Sup., 71 (1911), No. 1844, pp. 273, 274, figs. 5).—The method herein described consists essentially in sprouting the willow rods in a forcing house so that the peeling can be done during the winter months when labor is cheap and plentiful. This method was successfully employed at Laurel, Md., during the past season.

Eucalypts in Florida, R. ZON and J. M. BRISCOE (U. S. Dept. Agr., Forest Serv. Bul. 87, pp. 47, pls. 5, fig. 1).—This bulletin embraces results of a preliminary study relative to the species of eucalypts best adapted for culture in Florida. The soil and climatic conditions of Florida are compared with those countries in which eucalypts grow successfully, reference is made to the early introduction of eucalypts into Florida, and data are given on the species now growing in the State, together with a list of species suitable for various sites, and suggestions relative to methods of planting most suited to Florida conditions. The bulletin concludes with a tabulated list of eucalypts suitable to
Florida, showing the quality of timber, growth, and uses under native conditions, and their possible range in Florida.

The authors point out that the feasibility of commercial planting in Florida is as yet undetermined.

Memorandum regarding leading eucalypts suitable for India, F. Booth-Tucker (Agr. Research Inst. Pusa [India] Bul. 21, 1911, pp. 9).—A list is given of some 34 eucalypts suitable for India, including explanatory notes relative to each, general notes relative to eucalypts, and notes on planting and felling.

Australian plants suitable for gardens, parks, timber reserves, etc., W. R. Guilfoyle (Melbourne and London [1911], pp. 478, pls. 218).—This work contains directions for sowing and raising Australian seeds; the treatment of Australian plants in gardens; an alphabetically arranged table for Australian plants, giving the botanical name, authority, common name, and a description; a list of eucalypts, showing the confusion of common names; and a list of the principal common names of Australian plants with their botanical names.

The effect of nitrate of soda upon the flow of Ceara latex, R. D. Anstead (Planters’ Chron., 6 (1911), No. 15, pp. 203–205).—The author reports a preliminary experiment conducted by G. L. Newbery in Coorg in which the results obtained, although not conclusive, indicate that the flow of latex and yield of rubber is increased by the application of nitrate of soda, thus appearing to confirm the results reported by Wilcox (E. S. R., 22, p. 645).

Experiments are to be conducted on a larger scale.

Rubber-growing industry of the Philippine Islands.—Cost of production and profits, D. C. Worcester (War Dept. [U. S.] Bur. Insular Aff. [Pamphlet], 1911, pp. 24, pls. 16).—This consists of a compilation of information secured from different branches of the Philippine administration and from other sources relative to the present status of the rubber industry in the Philippine Islands. An estimate of the expenses and profits is given for a period of 11 years on a 1,000-acre plantation, the whole area to be planted by the end of the fourth year. Other information relative to the cost of land, clearing, planting operations, etc., is included.

Forest products of the United States, 1909 (Bur. of the Census [U. S.], Forest Products 1909, pp. 178, dgms. 3).—This consists of a statistical review compiled by the Bureau of the Census in cooperation with the Forest Service of this department relative to the production, consumption, imports, and exports of various forest products during 1909. The quantity and value of lumber, lath, and shingles is shown both by species and by States. The other products considered are crossties purchased, pulp-wood consumption, tanbark and tanning extract, slack cooperage stock, tight cooperage stock, veneers, poles, cross arms, brackets, insulator pins, and wood distillation. A short appendix is added relative to the production of naval stores.

The estimated total value at the point of manufacture of the domestic forest products in 1909 amounts to approximately $1,250,000,000, or an increase of 19 per cent over the 1908 estimate.

Austria-Hungary's timber trade and export, M. von Engel (Osterreich-Angehrs Hokhandel und Hokerport. Vienna, 1910, pp. 48, tables 2, dgms. 1).—A commercial and trade review of the timber industry in Austria-Hungary, including statistics relative to the export of raw timber and various manufactured products to different countries.
Industrial materials: The woods, edited by P. Krais (Gewerbliche Materialkunde: Die Hölzer. Stuttgart, 1910, vol. 1, pp. XVI+782, figs. 101).—This is the first of a series of volumes to be issued on industrial materials.

The present volume is a handbook of information on wood as a material. The subject matter was prepared by 21 authors and deals with the various woods from the standpoints of forestry, botany, trade, commerce, statistics, freight, and shipping; wood testing; the detection and correction of diseases and defects; wood coloring, embellishing, preservation, and working; and the application of woods to various purposes.

Wood-pulp testing at the forestry court cellulose laboratory, United Provinces Exhibition, W. Raitt (Indian Forester, 37 (1911), No. 1-2, pp. 30-34).—Methods of determining the paper-making value of inferior woods of the United Provinces are described and a list is given of those woods which have yielded at least 40 per cent of bleachable pulp with a soda consumption of not more than 20 per cent.

Oxidizing enzymes and their relation to sap stain in lumber, I. W. Bailey (Bot. Gaz., 50 (1910) No. 2, pp. 142-147; abs. in Chem. Abs., 5 (1911), No. 5, p. 897).—This work shows that sap stain in lumber is brought about by fungi and by chemical oxidation induced by the enzymes. It could be prevented in alder, birch, and cherry woods by treating the sapwood with boiling water.

Forest fires: Causes, losses, remedies (Bul. Soc. Cent. Forest. Belg., 18 (1911), Nos. 3, pp. 153-167; 4, pp. 229-240).—This is a report to the Belgian minister of agriculture of an investigation conducted by a special commission of the Superior Council of Forests, relative to the causes and losses from forest fires. Recommendations for the control of forest fires are presented.

The capital value of Württemberg state forests, Schickhardt (Allg. Forst u. Jagd Ztg., 87 (1911), Apr., pp. 118-126).—This is a discussion of methods for determining the capital value.

Contribution to the knowledge of the dynamic occurrences in the moving of timber on a timber slide, F. Angerhoifer von Almberg (Centbl. Gesam. Forstw., 37 (1911), No. 4, pp. 161-179, figs. 16).—The author here elaborates a modification of the law of inclined planes with special application to the motion of timber in timber slides, including such phases as rate of fall, rapidity, friction, and curve radius.

Forest railways for the extraction of timber in Burma, F. A. Leete (Indian Forester, 37 (1911), No. 1-2, pp. 34-54, pls. 2).—A self-balancing monorail system used in the transportation of logs is described.

Preliminary study of forest conditions in Tennessee, R. C. Hall (Tenn. Geol. Survey Bul. 10, Extract A, 1910, pp. 56, pls. 13, maps 2).—The results are given of a preliminary study conducted by the Forest Service of this Department in cooperation with the Tennessee State Geological Survey. The general condition of the forests, the various timber industries, and the forest regions are described, a number of special forest problems are discussed, and a forest policy for the State is recommended. A list of trees native to Tennessee, together with growth tables of white and chestnut oaks, is appended.

It is estimated that about 35 per cent of the total area of the State is in forests, and that a large part of this land is best suited for growing timber. The preservation of the forest, especially on steep slopes, the establishment of a fire protective system, the creation of state forests, and the employment of a state forester are recommended.
Seventh annual report of the state forester of Massachusetts, F. W. Lane (Ann. Rpt. State Forester Mass., 7 (1910), pp. 115, pls. 14, map 1).—Introductory considerations deal with the organization and staff of the forestry department, recent protective legislation enacted, publications of the department, and other miscellaneous subjects. Part 1 reviews the general forestry operations of the department, including the examinations of woodlands and assistance rendered to owners, reforestation and forest nursery work, and forest fires for the year and protective measures used, and concludes with a statement of expenditures and receipts for the year ended November 30, 1910.

Part 2, giving the year's results in the suppression of the gypsy and brown-tail moths, is noted on page 257 of this issue.

Report of the superintendent of forestry, R. S. Hosmer ([Bient.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1909-10, pp. 17-55, pls. 8).—This is a report for the biennial period ended December 31, 1910, relative to the management of Hawaiian forest reserves, forest extension, and miscellaneous forestry work. Reports of district foresters are appended, together with a summary of recommendations for the extension and improvement of forest operations.

According to the tabular data corrected to February 10, 1911, there are 23 forest reserves in Hawaii, comprising 575.154 acres, of which 358.547 acres are government land. A total of 537,351 trees was planted in 1909 and 725,022 trees in 1910, mainly by corporations. The experimental planting of Temperate Zone trees in higher altitudes by the Forest Service of this Department is being continued. During the last two years no serious forest fires have occurred.

Report of the forest nurseryman, D. Haughs ([Bient.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1909-10, pp. 56-66, pl. 1).—This is a progress report on work done during the biennial period ended December 31, 1910, at the Government Nursery, Makiki Experiment Station, Tantalus Forest Station, and Nuuanu Station.

Report of the botanical assistant, J. F. Rock ([Bient.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1909-10, pp. 67-88, pls. 12).—This is a progress report on the botanical exploration of the Hawaiian Islands, including the work of establishing a herbarium of native trees, shrubs, and plants. Notes are given on the flora observed in different sections of the islands.

Progress report of forest administration in Coorg for 1909-10, C. McCarthy (Rpt. Forest Admin. Coorg, 1909-10, pp. 8+12).—This is the usual annual report relative to the constitution, management, financial results, and administration of the state forests in Coorg. The more important data relative to alterations in areas, forest settlements, surveys, working plans, protection, grazing, and other phases, together with yields, returns, revenues, and expenditures are appended in tabular form.

Forest administration in Württemberg, F. Graner (Die Forstverwaltung Württembergs, Stuttgart, 1910, pp. 200).—A detailed account is given of the administration of the forests in Württemberg. The successive divisions of the text take up the forest growth and natural conditions of the country, forest districts and working regulations, forest and hunting legislation, the organization of the forest service, detailed management of the state forests, and forest statistics, including both state and corporation forests.
DISEASES OF PLANTS.

The results are given of confirmatory inoculation and cross-inoculation experiments with the crown gall organism from the daisy (Chrysanthemum frutescens), arbutus, grape, alfalfa, peach, rose, quince, beet, hop, chestnut, poplar, and apple. The relationship of crown gall to hairy root is discussed, and experiments with the hairy root organism reported. The morphological and cultural characters of the causal organism as isolated from the crown gall of the daisy are described in full; the characters and observed differences in crown gall organisms from various sources are also noted. The authors discuss the question of species, varieties, and races of crown gall organisms, structure and growth of the tumors, chemical and physical changes produced in the gall and on adjacent but not directly involved tissue, physiological effects, losses due to the disease, and the best methods of dealing with it.

It is stated that crown gall is a disease common in nurseries on the roots and shoots of various plants and which may persist on the plants after their removal to orchards, vineyards, gardens, and hothouses; it also occurs on various field crops. The causative organism, at least that for the daisy galls, is a white schizomycete, Bacterium tumefaciens (E. S. R., 18, p. 950). This organism does not produce open cavities in the host, but seems to be present in small numbers in the living cells, causing a rapid proliferation, especially in soft and rapidly growing tissues. Cross inoculations with the daisy organism have produced tumors on many species in widely separate parts of the natural system (Composite to Salicaceae). Schizomycetes grown from natural galls of the peach, apple, rose, quince, honeysuckle, arbutus, cotton, poplar, chestnut, alfalfa, grape, hop, beet, salsify, turnip, lettuce, and willow have been isolated, which closely resemble (as grown on agar) B. tumefaciens of the daisy, and some eight of which are able to produce tumors on the daisy and other plants, indicating that crown gall on all of these hosts is due to a polymorphic species, rather than to several distinct species.

Hard and soft galls and hairy root seem to be due to the same organism. It is claimed that crown gall is a disease which progresses slowly, stunting the plant at first, and finally destroying it unless removed by pruning or by the development of increased resistance of the host. Rigid state inspections and the rejection of diseased nursery stock are recommended.

These abnormal growths of plants designated as tumors or galls are believed by the senior author to be like malignant animal tumors in various particulars, such as permanent and very rapid new growth of affected tissues, enormous round-celled or spindle-celled hyperplasia, great reduction of the amount of conductive tissues, early necrosis with renewed growth at the margins, frequent recurrence after extirpation, extension of the disease to other parts by metastases, etc.

In the course of investigations on crown gall, a new disease of the sugar beet was discovered, due to a yellow schizomycete for which the name Bacterium beticolum n. sp. is proposed. The disease is called tuberculosis of the beet, and is characterized by overgrowths of a coarse nodular nature which soon disintegrate, leaving small cavities in the tissues.

Some troubles of New York plants, F. H. Hall (New York State Sta. Bul. 328, popular ed., pp. 12, figs. 2).—This is a popular edition of Bulletin 328
In which apple troubles, beet leaf spot, cherry rot and mildew, hop mold (Spharotheca humuli), frost injury to trees, pear troubles, Rhizoctonia on potatoes, and raspberry cane blight are especially discussed.

On the air infection of ergot and the dissemination of plant diseases by means of temperature currents, R. FALCK (Ztschr. Forst u. Jagdw., 43 (1911), No. 3, pp. 202-227, figs. 4).—The author discusses the influence of air and temperature currents on the dissemination of fungus spores in general, and of Claviceps in particular, under 3 headings, viz (1) the spore discharge from the ascus, (2) the further distribution of the discharged spores by temperature currents, and (3) the infection of rye by wind-blown ascospores of C. purpurea.

On the mechanical measurement of the resistance of grains to disease, F. STRAŇÁK (Deut. Landw. Presse, 38 (1911), No. 18, pp. 299, 310, fig. 1).—The author figures and describes an instrument for determining the strength and hardness of the cuticle and outer layers of the stems of grains. By this method it is claimed that a fairly accurate estimate of the disease resistance of various species and varieties of grains can be obtained.

On the longevity of barley loose smut (Ustilago hordei) in infected seed, H. ZIMMERMANN (Ztschr. Pflanzenkrank., 21 (1911), No. 3, pp. 131-133).—The results are given of planting 1, 2, and 3 year old barley seeds from plants which had been exposed to loose smut infection.

It was found that the seeds of susceptible varieties of barley which were smut infected when planted gave smutty ears, whether planted the first, second, or third year. It thereby showed that the smut mycelium in the barley grain can survive a three-year period of rest and, when subjected to the proper conditions for growth, may develop and produce smutty barley heads.

The influence of bunt on the shape of the wheat head, K. MICZYŃSKI (Ztschr. Landw. Versuchsw. Österreich., 14 (1911), No. 3, pp. 232-234, fig. 1).—Attention is called to the elongation of the heads of wheat attacked by stinking smut, in which the diseased heads are nearly twice the length of normal healthy ones.

Is Neocosmospora vasinfecta the perithecial stage of the Fusarium which causes cowpea wilt? B. B. HIGGINS (North Carolina Sta. Rpt. 1909, pp. 100-116, figs. 16).—The author gives the results of a series of cultures on various media of the cowpea wilt organism, F. vasinfectum, obtained from the interior of diseased cowpea vines, and of N. vasinfecta obtained from the exterior of cowpea stems which had been killed by the wilt.

The Neocosmospora cultures were made from perithecial material and were grown on several different culture media and for several generations, including pure mycelial, conidial, and ascosporic cultures all from one original perithecial culture.

The internal Fusarium cultures were obtained by aseptic transference of the mycelium from inside the stems to plates of cowpea-leaf agar. The asegerous fungus (N. vasinfecta) showed the following characters: Perithecia always present; mycelial growth slow, never pure white, scatly, and usually strict; macroconidia and chlamydomspores never present; bright colors (red, yellow, pink, or purple) not produced in any substratum; yellow spore clusters absent; and growth not occurring below the surface of the gelatin.

On the other hand, the internal fungus (F. vasinfectum) showed perithecia never present; mycelial growth rapid and profuse on rich media, aerial, floccose, and on most media, pure white; chlamydomspores present in all old cultures; bright colors produced on starchy foods; yellow spore clusters developed on agar, potato, and stems of cured cowpea hay; and growth produced below the surface of the gelatin.
In the light of the above facts the author concludes that for the present and until evidence is found to the contrary, Neocosmospora should be regarded as simply an accidental saprophyte, having no relation to the wilt of cowpeas or to the internal fungus (*F. vasinfectum*), which is probably the true cause of the wilt.

**A new disease (Sclerotinia) of the mangold, E. S. Salmon** (*Jour. Southeast. Agr. Col. Wye, 1909, No. 18, pp. 328–333, pls. 2*).—Attention is called to a storage rot of mangolds which in its earlier stages produces dark brown or blackish discolorations of portions of the interior of the root. Later, definite areas on the surface of the root soften, turn brown, and finally culminate in a rapid rot which destroys the entire root.

An examination of the discolored interior parts of the roots showed the presence of a fungus mycelium which penetrated the cells and occupied the intercellular spaces. These hyphae secrete two ferments, one which softens and dissolves the cell walls, while the other attacks and kills the protoplasm of the cells, turning it a brown color. By means of cultures the fungus is demonstrated to be a parasite belonging to the Botrytis genus. The disease was produced on both swedes and mangolds by inoculation with Botrytis conidia obtained from attacked mangolds.

As a remedy for this rot the author advises good ventilation and drainage of the storage pit, the rejection of all cut and bruised roots, and the avoidance of turnip, swede, mangold, or potato tops as a covering for the pit.

**Field experiments on the control of the potato scab, A. Bernhard** (*Deut. Landw. Presse, 38 (1911), Nos. 15, pp. 168, 169, figs. 3; 16, pp. 179, 180, fig. 1*).—The author reports the results of further experiments (*E. S. R.*, 23, p. 744) with sulphur in combating the potato scab. Marked beneficial results were obtained by using the sulphur in controlling the scab, in greater resistance to leaf-roll disease, and in obtaining yields of potatoes less subject to rot.

**Wart disease or black scab of potatoes, E. S. Salmon** (*Jour. Southeast. Agr. Col. Wye, 1909, No. 18, pp. 291–318, pls. 5*).—The author discusses the life history of the organism, characters of the disease, its continued dissemination, present distribution in England, Wales, Scotland, and Ireland, and the prohibition of exportation of potatoes on account of the prevalence of wart disease in Great Britain. It is claimed that under the existing laws and conditions farmlands generally are in great danger of becoming infected, that land once infected remains so for eight years, and that the use of sulphur, lime, and soot have proved absolutely valueless in combating the disease.

Wart disease of potatoes, and horse-radish disease in Cheshire, T. H. Middleton (*Bd. Agr. and Fisheries [London], Int. Div., Ann. Rpt. Proc. 1909–10, pp. 36–61, 66, 67*).—In a report on the Destructive Insects and Pests Order of 1910 the status of these diseases in England is given, including the present distribution of the wart disease of the potato, susceptible and resistant varieties, the results of experiments in soil disinfection with sulphur, lime, lime and sulphur, soot, and soot and sulphur, the results of variety tests at many centers of the disease as to the immunity or susceptibility of some 18 varieties of potatoes, and a brief note on the horse-radish disease in Cheshire.

In soil disinfection for controlling the wart disease of the potato, the treatment in every case was a complete failure. In the variety test the Langworthy type was found to be immune to the disease, while many other varieties under the same conditions of soil infection were badly diseased. It is stated that the disease is dangerous and very difficult to eradicate, and that cleanliness and the destruction of infected tubers, stems, and all other potato débris is a most important factor in combating the disease.
In discussing the horse-radish disease (*Pseudomonas campestris*), attention is called to the fact that only about one-fourth of the area formerly devoted to this vegetable is now planted. This reduction is due, it is claimed, to the ravages of this disease. Although it is usually supposed that *P. campestris* attacks all cruciferous crops, yet growers were unanimous in their opinion that any other crop, such as cabbages, Brussels sprouts, etc., could be successfully grown on badly diseased land and invariably produce clean, healthy plants. Two forms of the disease are common, one in which the interior of the horse-radish roots throughout its whole length and the roots quickly become hollow, and the other in which the interior remains sound but the outer portions rot.

On diseases of sugar beets in 1910, O. Faltada (Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 40 (1911), No. 1, pp. 34–40, figs. 3).—The author gives the distribution and relative intensity of the following diseases of sugar beets in Austria-Hungary: Damping off, heart or dry rot, root rot (*Rhizoctonia violacea*), crown gall, downy mildew, and leaf spot.

In discussing the crown gall of the sugar beet the theories of several investigators as to the cause of the disease are given, together with a description of the structure of the tumor.

Seed beds of sand as a means of combating the root rot (Thielavia basicola), M. Benincasa (Bol. Tcc. Collir. Tabacchi [Scalfati]. 10 (1911), No. 1, pp. 3–22, figs. 7).—The author compares the results of experiments on using ordinary garden loam, pure sand, and a volcanic cement pumice (pozzolana griglia di Tivoli) as materials for seed beds for tobacco in regions affected with the root rot organism (*T. basicola*). Artificial fertilizers were used on both the volcanic and sandy soil beds.

The conclusion is drawn from these experiments that the usual vehicle of infection is the soil commonly used in making the seed beds, and that heating this soil to a temperature of 90° C. is not sufficient to entirely prevent the rot in the seed beds. The seed beds of sand proved very efficient in controlling the rot, while the volcanic soil gave the best results of all, both as to vigor and growth of seedlings and in checking the rot. This was due apparently to the physical condition of the soil, which permitted a robust development of both the tops and roots of the tobacco plants by furnishing a warm and well aerated seed bed.

It is suggested that other similar substances, such as coal ashes, volcanic scoria, and other volcanic rocks, naturally or artificially pulverized, should act in the same manner as the volcanic material. As a means of controlling the disease in the field the author advises the use of resistant plants like those grown in the volcanic seed beds or in sand, and crop rotation, preferably with grain.

[Fruit diseases] Oreg. Agr. Col. Bul., 1. ser., 1911, No. 48, pp. 52, 54, pls. 2).—Attention is called to the prevalence of pear blight on both apples and pears, and a warning is given that if not better controlled a serious epidemic may occur. Apple scab is also reported as becoming troublesome in La Grande and Cove districts, while considerable so-called winter injury was found in the spring of 1910 in the vicinity of La Grande and Union.

Scab, Monilia, and white leaf spot on different fruit trees, G. Köck (Ztschr. Landw. Versuchsw. Österr., 14 (1911), No. 3, pp. 209–213).—On account of the abnormal weather conditions during 1910 these diseases were very prevalent on different kinds of orchard trees, and an opportunity was thereby afforded of observing the susceptibility or resistance of many varieties.
The author gives a list of the varieties of apples and pears that were observed to be susceptible or resistant to each of these fungi.

The red color of the fruit, and the scab of apples and pears, J. Eriksson (Ztschr. Pflanzenkrank., 21 (1911), No. 3, pp. 129–131, figs. 2).—The author takes issue with E. Voges, who in a recent article (E. S. R., 24, p. 450) claimed that red-skinned apples are more resistant to scab than other kinds. He cites examples of red and yellow skinned varieties of both apples and pears which were badly attacked by this disease, not only the fruit but even the leaves being badly injured in some instances.

Black spot or apple scab, E. S. Salmon (Jour. Southeast. Agr. Col. Wye, 1909, No. 18, pp. 267–270, pls. 3).—The author gives the history of an attack by apple scab in an orchard where for several years the disease was neglected until all the fruit of certain susceptible varieties was ruined, yet which was practically controlled by judicious spraying with a 4:100 mixture of copper sulphate in February, followed by two or three sprayings with Bordeaux mixture.

Cooperative spraying at the Cove for apple scab (Org. Agr. Col. Bul., 1, ser., 1911, No. 48, p. 29).—The results are reported of experiments undertaken to determine the most effective time to spray with lime-sulphur mixtures for apple scab under the local climatic conditions. Fourteen-year-old trees of the Mammoth Black Twig, which is a very susceptible variety, a 1:15 solution of lime-sulphur mixture, and a hand pump with a pressure ranging from 100 to 125 pounds were used in these tests.

The results indicate that the proper time to spray under the local conditions is when the blossoms are showing pink, which occurs about the 1st of May, and that only the one application is necessary, as later sprayings showed no evident advantage over the first in controlling the scab.

Tumors on apple trees, P. Sorauer (Ztschr. Pflanzenkrank., 21 (1911), No. 1–2, pp. 27–36, pls. 2).—The author claims that the twig swellings or tumors often seen at the base of the side twigs on apple and pear trees are not due primarily to capsids (Orthotylus nassatus), as is usually supposed, but are initiated by frost injuries to the inner cells of the shoot, which later are attacked by the capsids.

Pruning and the inoculation of the olive knot bacteria, L. Savastano (Bot. Arbor. Ital., 6 (1910), No. 1, pp. 30–33).—From observations and experiments the author concludes that the infection of healthy olive trees with the olive knot organism by means of pruning tools rarely occurs. Nevertheless, it is suggested that the tools while being used should be sterilized.

Nine districts are named where the disease is thoroughly established or is known to exist. Instances are recorded of infection from returned empty baskets which had contained diseased fruit, from infected clothes and boots of workmen, from wind-carried spores, from the introduction of diseased plants, and from reinfection from winter spores dropping on the soil.

The best remedy found for controlling the disease was late fall or early winter pruning, in which all old wood, unnecessary branches, suckers, and the tips
of shoots the ends of which were covered with mildew, were removed and burned. Winter spraying with Bordeaux mixture and with "sour" Bordeaux mixture (from 4 to 5 per cent solution) did not prevent fruit infection by the mildew.

The American gooseberry mildew, E. S. Salmon (Jour. Southeast. Agr. Col. Wye, 1909, No. 18, pp. 271—293, pls. 4).—A history is given of the spread of this disease in Kent, England, the damage done by it, the extent of the infected area and remedies used for its control and the success obtained by their use.

It is claimed that the disease obtained a foothold through several growers of gooseberries concealing its presence on their plantations until the disease became very serious and widely disseminated. It is stated that no success can be obtained in eradicating it unless the winter pruning of infected shoots is done quite early and very thoroughly. For summer control to prevent further infection by conidia, the use of freshly mixed potassium sulphid is claimed to be the only sure remedy.

The Sclerotinia (Botrytis) disease of the gooseberry, or die back, E. S. Salmon (Jour. Southeast. Agr. Col. Wye, 1909, No. 18, pp. 319—327, pls. 5, fig. 1).—A description of and remedies for this disease are given.

The author claims that the sclerotia formed by this fungus produce both conidia and ascospores. The prompt removal and destruction of all dead and dying bushes carried out for a few seasons is claimed to be more efficacious in stamping out this disease than spraying.

Teratological forms of Oxycoccus macrocarpus, C. L. Shear (Science, n. ser., 33 (1911), No. 840, p. 194).—The author reports a malformation of the cranberry plant of both economic and scientific interest, occurring at Grand Rapids, Wis. The flowers become erect instead of drooping, and the calyx and corolla, and frequently the stamens and pistil, are changed into leaflike structures.

No insects or fungi have been found to bear a causal relation to the malformation, and the trouble is supposed to be caused by a prolonged and excessive stimulation of vegetative growth.

On the abnormal branching of Asparagus sprengeri, A. Y. Grevillius (Ztschr. Pflanzenkrank., 21 (1911), No. 1—2, pp. 17—37, figs. 7).—Attention is called to an abnormal branching of this ornamental plant, in which at the base of many of the main branches one or more knotlike processes up to 2½ centimeters in diameter developed. These deformities were usually found to occur on plants growing in an atmosphere saturated with moisture, in a soil thoroughly watered, and in poorly ventilated places (greenhouses). The malformation occurs in both rich soil and poor soil, while instances have also been noted of its occurrence on plants growing in the open.

The mildew of the oak, M. Mangin (Rev. Eaux et Forêts, 50 (1911), No. 8, pp. 225—239).—After giving the opinions of various investigators as to the taxonomic position of this serious European oak mildew, the author discusses its characters and development, the species of oak attacked, the methods of propagation, the damage done by it, and possible remedies.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

of which two are described as new to science. A brief account is given of the distribution, habits, and economic relations of muskrats, a more extended account of which, by D. E. Lantz, has been previously noted (E. S. R.., 23, p. 356).

A key to adult muskrats in fresh pelage, a bibliography of 55 titles, and a colored map showing the distribution of muskrats as known at present are included.

A study of the food of moles in Illinois, J. A. West (Bul. Ill. State Lab. Nat. Hist., 9 (1910), Art. 2, pp. 11-22).—"The contents of the stomachs here reported have shown perhaps a greater amount of insect food and somewhat smaller ratios of earthworms than those examined by other writers, but there is a substantial agreement to the effect that half or more of the food of the mole consists of insects and their larvae, most of them noxious. So far as its food is concerned, the mole is thus beneficial, on the whole. There is no direct evidence that it will eat potatoes or other tubers, but circumstantial evidence on this point is so strong that the mole must remain under suspicion, even admitting that mice of herbivorous habit may occupy mole runs in fall. In this paper it is shown, for the first time, that corn may form an important item of the food of moles; that recently planted corn is sometimes destroyed by them; and that if numerous in corn fields in spring, they are capable of doing considerable damage there."

A plague-like disease of rodents, G. W. McCoy (Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Bul. 43, 1911, pp. 53-71).—"A disease which presents lesions very similar to those of plague has been found among ground squirrels. The disease is readily transmitted to guinea pigs, mice, rabbits, monkeys, and gophers, and plague-like lesions are produced in at least some of these animals. Rats are but moderately susceptible to the infection. Cats, dogs, and pigeons appear to be immune.

The disease may be transmitted artificially by subcutaneous, cutaneous (vaccination), nasal, and intraperitoneal inoculation. The mode of transmission in nature is unknown, but there is some experimental evidence that suggests that fleas may serve as carriers. The disease probably is not spread by mere contact of healthy with infected animals. The infectious agent has not been isolated. On account of the number of species susceptible, it seems likely that it is bacterial, not protozoan. The causative agent is present in the circulating blood, as well as in the various tissues where it causes focal lesions. The thermal death point of the organism as it is found in the animal's body is between 55° and 60° C. Several observations appear to indicate that the disease is a febrile one."

A contribution to the study of rat leprosy, D. H. Currie and H. T. Hollmann (Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Bul. 41, 1911, pp. 13-32).—Following a review of the literature relating to the subject notes by the authors on 12 cases of rat leprosy are recorded. The conclusions drawn are as follows:

"In some cases of artificially acquired rat leprosy the onset is with bronchopneumonia, accompanied by a septicemia and without other demonstrable lesions. In other cases of this disease pneumonia is a very early lesion, but we can not positively state that it is always the first lesion. The animal may die in the pneumonic stage before other lesions present themselves or it may develop pneumonic symptoms and recover from the same only to develop later the well-known lesions of chronic rat leprosy; or, again, the pneumonia may persist until after the development of the lesions of the skin and abdominal visera. During the stage of the disease in which the animal is very ill certain mites (Laelaps echidinus) were found to be very numerous on the ani-
nals’ bodies. During the stage of the disease in which septicemia is marked these mites’ digestive tracts contain the bacilli of rat leprosy in considerable numbers, and therefore these parasites may be one means of transmitting the disease. This latter probability, however, is, of course, not proven.”

A bibliography of 17 titles relating to the subject is appended.

Report of the state entomologist, T. B. Symons (Rpt. Md. Hort. Soc., 12 (1969), pp. 158-164, pls. 2).—It is stated that 289,652 of 1,976,996 orchard trees inspected during the year were found infested with San José scale. Nursery inspection and public spraying work is reported on and a brief account is given of the occurrence of a few of the more important insect pests, and of dipping and spraying experiments, etc.

Report of entomologist, R. I. Smith (North Carolina Sta. Rpt. 1909, pp. 32, 33).—Experiments conducted with the common red house ant, Monomorium pharaonis, which in August became abundant in the agricultural building, demonstrated that they may be kept off laboratory tables, desks, shelves, etc., by the use of a saturated solution of bichlorid of mercury, one application being effective for several weeks, except for an occasional stray individual. Brief statements are given of work with corn weevils and San José scale.

Insect pests [in the West Indies, 1909-10], H. A. Balloff (West Indian Bul., 11 (1911), No. 2, pp. 85-94).—The author reports upon the more important insect pests of the year that attacked sugar cane, cotton, cacao, citrus, rubber trees, sweet potato, green manure crops, ground nuts, and onions.

Report of economic zoology for the year ending April 1, 1909, F. V. Theobald (Jour. Southeast, Agr. Col. Wye, 1909, No. 18, pp. 87-196, pls. 34, figs. 2).—In this report the author considers the insects and other enemies which during the year were injurious to domesticated animals, fruit trees and bushes, corn, grass lands, root crops, pulse, hops, vegetables, flowers, forest trees, and stored goods, or caused annoyance to man. A list and synoptic table of, and notes on, the British Culicidae are included. It is said that by far the worst attacks during the year were those of the edeworm and frit fly in corn.

Brief mention is made of a plague of noctuid caterpillars (Laphygma eximpta) that visited the town of Bulawayo, Rhodesia, in December, 1907.

Destructive Insects and Pests Order, 1910 (Ed. Agr. and Fisheries [London], Intel. Div., Ann. Rpt. Proc. 1909-10, pp. 25-69, pls. 2).—The pests scheduled under the Destructive Insects and Pests Order of 1910 are discussed, namely, the grape phylloxera, San José scale, Mediterranean fruit fly (Ceratitis capitata), Colorado potato beetle, large larch saw fly (Nematus erichsoni), potato moth (Lita solanella), gypsy and brown-tail moths, nun moth (Liparis monacha), cherry fruit fly (Rhoagoletis cerasi), narcissus fly (Macrodon equestris), black knot, wart disease of potatoes (Synchytrium endobioticum), tomato leaf spot (Septoria lycopersici), and melon or cucumber canker (Mycosphaerella citrtullina).

The unscheduled pests noted (pp. 62-69) are the felted beech coccus (Cryptococcus fagi), beetles on osier beds (Galerucella lincola, Phyllodecta vitellina, etc.), horse-radish disease in Cheshire due to Pseudomonas campestris, “leather-jacket” or crane fly larvae which caused injury to oats in Lancashire, frit fly inquiry, and bee disease in the Isle of Wight.

The principal insects injurious to horticulture during 1908-9, M. H. Swenk (Ann. Rpt. Nebr. Hort. Soc., 40 (1909), pp. 75-128, pls. 16).—In this report the author deals with insect pests of fruits, shade trees, and ornamentals that came to his attention during the two years prior to April 1, 1910.
The mulberry borer (Dorcaschoma altercatum) is stated to have been a serious pest on the mulberry tree in the vicinity of Lincoln during the spring of 1908. Fifty per cent of the larvae working in the stems were found to be parasitized by a braconid. In investigations made in the forest reserve near Halsey July 10, it was found that about 35 per cent of the new tips of the young jack pine (Pinus densiflora) and Scotch pine (P. sylvestris) were affected by the pine-tip moth (Ectria frustana), and practically all of them were dead. A brief report of the results of studies of the parasitism of the white-marked tussock moth in 1908, prepared by C. H. Gable is presented. The occurrence of and injury caused by numerous other species is briefly considered.

Report of the government entomologist for the year 1909-10, C. C. Gowdey (Rpt. Gort. Ent. Uganda, 1909-10, pp. 24).—The author here reports upon the insects that were injurious during the year to various crops in Uganda, as follows: The Mediterranean fruit fly (Ceratitis capitata), coffee beetle (Stephanoderes coffee), Ceroplastes ceriferus, and Ceroplastes n. sp., which were the source of injury to coffee; the cacao fruit fly (Ceratitis punctata), Stictococcus dimorphus, cacao beetle (Adoretus hirtellus), and Grylotalpa africana, which injured cacao; the citrus psylla (Triacca sp.) the orange butterfly (Papilio demodocus), scale insects (Mytilaspis gloveri and M. citricola), and plant lice (Aphis citri), attacking citrus; cutworms injurious to garden crops: the cotton stainer (Oryzecus hyalipennis) and the cotton bollworm (Earias insulana), which attacked cotton; the castillon borer (Luesida leposa), Termes hellicosus, and Pulvinaria psidii, which were injurious to rubber; the sweet potato caterpillar (Acræa terpsichore), the sweet potato weevil (Cylas formicarius), and Conchylocenta punctata parnascus, which injured sweet potatoes; the palm weevil (Rhynchophorus phenicis) and Aspidiotus cydonia, which injured palms; and the Congo floor maggot (Auchmeromyia lutecola).

Report of the entomologist [of Ceylon], E. E. Green (Admin. Rpts. Roy. Bot. Gard. Ceylon, 1909, Ed. Sci., and Asst., pt. 4, pp. 4–6).—In this report brief accounts are given of the occurrence and injury caused by some of the more important insects, particularly the shot-hole borer (Xylocoris fornicatus). A new rubber pest that caused considerable damage to young rubber plants on one estate was found to be the slug, Mariabella dussamieri.

Some insect pests of the sugar cane, J. J. Quelch (Timachi, Brit. Guiana, n. ser., 1 (1011), No. 1, pp. 9–14).—Mention is made of 10 insect enemies of the sugar cane in British Guiana and of 12 birds that assist in combating them.

Insects injurious to the peach trees in New Jersey, J. B. Smith (New Jersey Stas. Bul. 235, pp. 3–53, pls. 4, figs. 14).—Nine insects that are the source of injury to peach trees in New Jersey and require treatment in the orchard are here considered, namely, the peach borer, plum curculio, San José scale, terrapin scale, black peach aphis, green peach aphis, shot-hole borer, peach twig moth, and rose chafer. Brief accounts being given of the life history, injury, and remedial measures for each.

The peach borer, which occurs throughout the State, is much more injurious in the lighter soils of the southern section of New Jersey than in the more stony, hilly North. A report of studies of the life history and remedial measures for this borer, conducted by the author, has been previous noted (E. S. R., 10, p. 656).

Observations made during the seasons of 1909 and 1910 indicate that the appearance of adults prior to July 1 is exceptional. It is estimated that not 10 per cent of the eggs actually laid ever produce larvae that secure entrance to feeding quarters in the tree. From collections made during the season of 1910, it appears that there are five stages between the eggs and full grown
larva. "Even the most-advanced caterpillars do not mature until well along in June, while some of those that hatched very late do not complete their growth in time to transform the first season, but lie over a second winter, practically full grown, and do some little feeding at the beginning of the next summer. ... No cocoons at all were found, in 1910, on June 24; July 8 they were to be found in some numbers, and on July 13 moths had begun to emerge, making an extreme of 19 days, of which perhaps 15 may be credited to the actual pupal stage."

Every tree set out should be closely examined for signs of the borers or borer work and every tree that may have a borer in it discarded. "An existing or already infested orchard should be carefully examined at least twice in each year; as late as convenient in fall, and again in the following end of May or early June. In the fall examination the earth should be removed from around the base of the trees to a depth of at least 6 and preferably 8 inches and every sign of a wound or place from which gum exudes should be investigated." Examinations should again be made between the end of May and the middle of June, by which "time the borers that wintered in the second or third stage will have reached the fourth stage at least and will show signs of their presence even if pretty well down. Their feeding will not have been sufficient to have caused serious harm, and careful work at this time should result in the elimination of at least 95 per cent of all the borers present in the orchard. Leave the base of the tree exposed for a few days now, to toughen the outer bark, and then, before again drawing up the soil, spray very thoroughly with a lime-sulphur, arsenate of lead mixture, to which an excess of lime has been added. Use 1 pound paste arsenate of lead to every 5 gallons of lime-sulphur, or 1 pound of dry arsenate to every 10 gallons of lime-sulphur, and apply with all the force possible to the exposed crown and for a distance of 18 to 24 inches above the surface. Then cover and hill up at least 6 inches around the trunk after the application is thoroughly dry. The strength of the lime-sulphur wash may be that of the ordinary winter spray with double the required amount of lime. ... The lime and sulphur wash will weather above ground and may carry with it the arsenate of lead; therefore, it seems desirable to make at least two additional applications to the trunk above ground, say one about July 10 and the other about August 1. Below ground the soil and moisture will maintain the poisonous coating for the entire season."

As a result of observations and experiments made during the seasons 1909 and 1910 and after going over records of previous experiments, the author concludes that mechanical coverings of paper and other materials are not of sufficient value to be further recommended. It is pointed out that a protective covering must be in place not later than July 1, and must be maintained intact until September 1 at least, if all borers are to be excluded. The various combinations of clay, lime, cowdung, soap, and other messes are all good if they can be applied well enough and cheaply enough to afford complete protection.

Egg-laying by the plum curculio begins in South Jersey by May 10. The eggs hatch in about a week, and the larval galleries and young larvae may be found in dropped fruit any time from May 20 to early July. The heavy part of the brood matures in mid-July as larvae and during early August as adults.

The terraphin scale is confined to Cumberland County, where it is more injurious than the San José scale and has led to the abandonment of orchards in some instances. The black peach aphids occurs throughout the State, but does injury only in warm light soils and mainly during the early life of the tree. The green aphids, which is always present to some extent everywhere in the State, only becomes seasonally and locally troublesome on younger trees. The peach twig borer has been found by the author throughout the State, and in
some seasons and localities it does noticeable injury and may stunt young trees to some extent.

Insects injurious to citrus fruits and methods for combating them. W. V. Tower (Porto Rico Sta. Bul. 10, pp. 7-55, pls. 5).—In this bulletin the author deals with 12 of the more important insect enemies of citrus fruits in Porto Rico, and their natural enemies, including methods of propagation and insecticides, with directions for their preparation and application.

The orange leaf weevil (Diaprepes spergleri) appears during May, June, and July, and again in November, there being two broods annually. The larvae feeds on the roots of the orange, in a few cases having been found damaging the trees to such an extent that the leaves turn yellow and drop off. The guava, avocado, mango, and rose are also food plants of the adult. "When this insect appears spraying should be resorted to with arsenate of lead, 4 pounds to 50 gallons of water. If there is a great deal of scab in the groves it is recommended that a fungicide be applied with the insecticide."

The small orange leaf weevil, a ravenous feeder on orange leaves, especially the new growth, is a pest that was first noticed in January and February, 1908, in the San Juan district and near Arecibo in groves planted in sandy soils. In 1908 all the beetles disappeared by March 1, but reappeared again in June and during the blossoming period were seen scarring the fruit. The eggs, which vary in number from 6 to 24, are deposited in clusters between the leaves. On hatching the larvae soon fall to the ground and feed on the roots of the orange trees. The treatment is the same as for the orange leaf weevil.

The May beetle (Lachnosterna sp.) is the source of injury more particularly noticeable in young groves, especially where the ground has been broken for the first time. It generally appears during April, May, and June and is a voracious leaf feeder. The caculo, the common name by which the larva of this beetle is known in Porto Rico, feeds on the roots of orange, sugar cane, and a number of common grasses, causing considerable destruction, often as many as 50 having been taken from about the base of a single young orange tree.

The orange dog, a papilionid caterpillar which has been found at the station during July and October, feeds on the leaves of the orange and when present in large numbers causes considerable damage as it is a ravenous feeder. Satisfactory results have been obtained in combating this pest by spraying with arsenate of lead, 3 pounds to 50 gallons of water.

The brown ant (Solenopsis geminata), which attends the white fly and the Lecanium scale, attacks the young, tender shoots and leaves of the orange when its natural food supply is cut off. The ants carry sand up about the base of the trees and when the food supply is scant they gnaw the bark where it is covered by their sand houses. Often when pineapples have been removed from between rows of orange trees the ants attack the latter in great numbers, scarring the trees, eating young, tender shoots, and cutting holes in the fruit. Carbolic acid emulsion is said to be the simplest and most inexpensive spray to be recommended in combating them.

The woolly white fly (Aleyrodus howardi) feeds upon the guava and orange and is attended by ants. A red spider feeds upon the essential oils of the orange, preferably on the under or shady side of the fruit or leaf, causing them to become rusty in appearance. The adult is readily held in check by sulphur sprays or by soap or kerosene emulsion. A rust mite closely resembling the Florida species and probably identical with it was first discovered on orange, grapefruit, and lemon in Porto Rico during the spring of 1909.

A preliminary account of the four species of scale described as the source of injury to citrus on the island has been previously noted (E. S. R., 22, p. 252). The purple scale which is present in all cultivated and wild groves on the island
is the most serious orange pest. Oviposition continues over a period of from 8 to 11 days, from 40 to 80 eggs being deposited. The incubation period is shorter than the period of oviposition, the first egg hatching before the last is laid. Incubation has been found at times, however, to require as many as 18 days. The adult males appeared in 5 weeks, while 7 weeks are required for the development of the females. The life cycle of the female is said to require from 8 to 9 and in some cases 10 weeks.

Infestation by the white scale (Chionaspis citri), which is generally found on the trunks and branches of old trees, usually starts at the base and gradually works up among the branches and often into the young twigs. The black fungus that parasitizes this scale is said to be rather slow in spreading in cultivated groves. Life-history studies at the station show that this scale requires the same length of time to develop as does the purple scale. "The most effective emulsions are kerosene with carbolic acid, 1 part of the mixture to 5 of water, and crude oil with carbolic acid, 1 part of the mixture to 15 or 18 of water."

The Florida red scale (Chrysomphalus aonidum), which is quite prevalent in citrus groves, is generally found on the leaves and fruit of the orange and lemon. It does not spread as rapidly as the purple and white scales but when found on the fruit is very difficult to remove. About 8 or 9 weeks are required for its development. The red-headed fungus (Sphorostilbe coccophila) has been found preying upon it. The treatment is said to be the same as for the purple scale.

The hemispherical scale, generally found on the small branches and leaves and occasionally on the fruit, attacks many ornamental plants but is not considered a serious pest as it is readily held in check by one or two sprayings of kerosene emulsion. It is attended by ants which distribute the young from place to place. It is preyed upon during the rainy season by a white fungus (Sporotrichum sp.).

Brief notes are presented upon beneficial fungi and methods of their introduction in combating scales. The red-headed fungus appears in the Bayamon district and is more prevalent there than the white-headed fungus. In the Pueblo Viejo district, however, the white-headed fungus has been observed in greater numbers than the red-headed fungus. It is said that the species that prey upon the purple scale spread very rapidly, whereas those which prey upon the white scale do so very slowly.

Windbreaks are discussed at some length, attention being called to the fact that there is not a grove on the island that does not need in some part more protection from wind than it has at the present time. The several causes of scarred fruit are discussed. Chafing by wind is shown to be an important factor; in one case the windy side of a tree showed 23 scarred and 234 unscarred fruit, while the leeward side showed 7 scarred and 210 unscarred.

Notes on spraying and spraying machinery and an extended discussion of insecticides and fungicides follow.

Notes on some coconut pests, P. L. Guppy (Proc. Agr. Soc. Trinidad and Tobago, 11 (1911), No. 2, pp. 164-171).—The data here presented relate to Brassolis sophore, the spiny coconut caterpillar (Hyperchiria sp.), a rhinoceros beetle, and Rhynchophorus palmarum, the larva of which is the well-known "gru-gru worm."

Insects of the greenhouse and their extermination, J. J. Davis (Trans. Ill. Hort. Soc., n. ser., 44 (1910), pp. 32-41).—The author here considers a few of
the more important insect pests that occur in the greenhouse, including the 
Sciaridae (Sciarinae) and the rose chafer (Corymbia rosacea), and the greenhouse white fly, the red spider, cutworms, of which Peridroma saucia is the most common, plant lice, thrips, of which Thrips tabaci is said to be the most abundant and troublesome in Illinois, the rose or oblique-banded leaf roller (Cucicrus rosaceana), and the greenhouse leaf-tyer (Phylleptus ferrugalis).

The mole cricket (Scapteriscus didactylus), A. Fredhomi (Proc. Agr. Soc. Trinidad and Tobago, 11 (1911), No. 2, pp. 153–163; abs. in Agr. News [Barbados], 10 (1911), No. 233, p. 106).—This is a general account of the life history, habits, and remedial measures for the mole cricket, which in Trinidad takes a prominent place among insect pests, it being the most destructive of those that occur in market gardens. Three of the most common birds in Trinidad, the Savannah blackbird (Quiscalus crassirostris), the tickbird (Crotaphaga ani), and Lanius pilulans feed freely on mole crickets and assist in checking more extensive depredations.

Poisonous baits are resorted to as remedial measures.

The Thysanoptera that attack Gramineae in Russia, D. M. Korolkov (Izv. Moskoc. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscow), 16 (1910), No. 3, pp. 192–205, figs. 11).—This is a report of investigations made of the thrips that attack grains and grasses in Russia. The work, which was conducted in cooperation with N. M. Kulagin, was carried on in the fields of the Moscow Agricultural Institute upon winter rye, wheat, oats, timothy, and other grasses.

Six species were found, namely, Anthothrips aculeatus, Limothrips denticornis, Physopous vulgatissimus, Aplecothrips rufus, A. nitidulus, and Chirothrips manicatus, the first four being the most important. A. aculeatus was found to feed on the ripe pollen and deposit its eggs on the flower apophyses.

The apple red bugs, C. R. Crosby and C. S. Wilson (New York Cornell Sta. Bull. 291, pp. 213–225, pl. 5, figs. 10).—The capsule bugs Heteroecus pinus and Lygidae mendax, to which the common names of apple red bug and false apple red bug, respectively, have been applied, have become a source of injury to apples in New York. Although observed on apples from time to time for a number of years, they did not become of sufficient importance to warrant particular study until the spring of 1908, when a serious outbreak was reported in an orchard at Syracuse, an account of which by M. V. Slingerland has been previously noted (E. S. R., 22, p. 654).

While the most conspicuous work of the red bug is found on the leaves, those that are badly punctured early in the season becoming curled and in some cases dropping off, yet this damage is very slight. A little later the bugs attack the tender leaves at the tips of the growing branches and frequently stop growth by their punctures. The principal injury, however, is caused by punctures in the young fruit. The bristles of the bug’s beak penetrate quite to the center of the young apples, the tissue around each puncture becoming discolored and hardened. Many of the punctured apples fall to the ground, others dry up on the trees, while the remainder mature but are badly deformed and rendered unmarketable. Sometimes a drop of gum oozes from each puncture. A grower at Waterloo states that during the past few years the injury in his orchard has amounted to about $1,000 a year, while another at Brockport estimates his yearly loss to be from $300 to $500. In 1909 the presence of aphids in great numbers made any estimate of the extent of red bug injury almost impossible.

101861°—No. 3—11—5
Both species are generally distributed throughout the apple-growing sections of the State and the red bug is recorded from Illinois. A species closely related to the red bug, *H. flavipes*, has been recorded by I. Nitobe from Japan, where it is a source of injury. The apple is the only food plant upon which the author has found these two red bugs feeding.

The eggs of both species are laid during late June or early July, being inserted their full length into the bark on the smaller branches, 2-year-old wood being preferred. All eggs definitely known to belong to the red bug were found inserted in a slit in the bark at the base of the fruit spurs, while those of the false red bug are usually inserted in pairs in the lenticels of smooth 2-year-old wood. The eggs of the red bug begin to hatch soon after the leaves of the fruit buds open and hatching is practically complete by the time the blossoms open; those of the false red bug hatch about one week later. Technical descriptions and drawings are given of the five nympha! stages passed by these species. Very soon after hatching the nymphs move to the young leaves on which they feed until full grown in case fruit is not available. Both species were reared to the adult stage exclusively on foliage. Usually when fruit is present the nymphs attack it as soon as set and sting it to death with their feeding punctures.

Attempts made to kill the delicate and tender nymphs at the time of hatching by coating the bark thoroughly with commercial lime-sulphur, diluted 1:8, and applied just before the time of hatching, failed, the nymphs maturing on the trees as abundantly as on those not treated. Experiments conducted in 1909 demonstrated that the nymphs are very hard to kill with either whale-oil soap or kerosene emulsion and that commercial whale-oil soap is very likely to burn young apple foliage. In experiments made in 1909 with commercial lime-sulphur, diluted 1:30, none of the nymphs was killed unless the liquid was applied so freely as practically to drown them.

In 1910 experiments with whale-oil soap and nicotine preparations were conducted on a larger scale. Neither homemade whale-oil soap free from combined alkali nor commercial brands were effective in killing the nymphs. Blackleaf diluted 1:65, Neko-fume diluted 1:700, and Blackleaf 40 diluted 1:816 were found effective when the nymphs were thoroughly wet with the spray. The addition of about 2 pounds of soap to each 50 gallons of liquid made it spread better and in a measure it lost its tendency to collect in small drops without wetting the insects. A grower at Waterloo, who used Blackleaf at the rate of 1 gallon in 100 gallons of dilute lime-sulphur to which arsenate of lead had been added reports excellent results in the control of the red bug.

In applying the nicotine preparation the first application should be made just before the blossoms open, while the nymphs are small, soft, and tender. As the eggs of the false red bug and some of those of the red bug hatch during the time the trees are in blossom, a second application may sometimes be necessary just after the blossoms fall, at which time the tobacco preparation may be added to the lime-sulphur and arsenate of lead as used for apple scab and the codling moth.

**Harlequin cabbage bug** (*Murgantia histrionica*), R. I. Smith (*North Carolina Sta. Rpt. 1909*, pp. 90–99, fig. 1).—This is a report of studies of the life history and habits of the harlequin cabbage bug, a paper relating to which has been previously noted (E. S. R., 21, p. 348).

Tabulated records of the oviposition of 14 hibernated individuals show that egg masses are deposited at periods varying from 2 to 15 days, with an average of about one mass every 4 days, 12 being the normal number of eggs in a mass. Eggs deposited the middle of April required an average of 11 days for incubation, while for eggs deposited the middle of May the average was about 6 days.
In hot summer weather, however, they may hatch on the fourth day. The length of life of the 14 hibernating females kept in confinement varied from 22 to 69 days, the last dying on June 11. Ninety-six was about the average number of eggs laid by each hibernating female, the maximum being 179 and the minimum 36.

The usual number of eggs deposited by the second brood is from 72 to 84. There is stated to be a variation in the duration of the young stages particularly in the fourth and fifth instars. The author’s records of bugs that hatched on August 24 and 25 showed the life cycle, exclusively of the egg stage, to cover from 57 to 65 days. Three full generations and possibly a partial fourth are all that are produced in the vicinity of Raleigh, N. C. Eggs deposited in the fall too late to hatch or bugs that fail to reach maturity before winter commences, do not live until spring.

On the leaf-hoppers that injure the sugar beet in Bohemia, H. Uzel (Ztschr. Zuckerindus. Böhmen, 35 (1911), No. 5, pp. 285-292).—The species here considered are Cicadula Sexnotata, Chlorita flavescens, C. solani, Euptyeryx carpini (=Typhlocyba pecta), and Philanæa sparnarius (=Aphrophora sparnaria).

Description of a new coccid species, Ceroputo ambigua, with notes on its life history and anatomy, D. T. Fullaway (Proc. Davenport Acad. Sci., 12 (1910), pp. 233-339, pls. 4).—It is stated that this scale insect is to be found on the salt marsh grass or pickle weed (Salicornia ambigua) that grows on the marshy flats of the bay region in the vicinity of Palo Alto, Cal.

Hæmatopius urius as an agent in the transmission of infectious diseases of the pig, N. Bernazky (Abs. in Centbl. Bakt. [etc.]. 1. Abt., Ref., 45 (1910), No. 20, p. 614; Vct. Rec., 23 (1910), No. 1139, pp. 37, 38).—The author observed that upon a farm where hog cholera prevailed the hog louse (H. urius) passed from the dead animals to the straw and thence to other pigs. Lice were collected from infected pigs and placed upon 4 pigs of from 10 to 11½ kg, in weight that had been obtained from a region free from swine fever, 19 lice being placed upon each pig.

All of the 4 pigs became ill in from 12 to 14 days, showing diarrhea and becoming emaciated. Two of the pigs died after 17 and 19 days, respectively, while the other two remained alive until the thirty-first and thirty-fifth days after the commencement of the experiment. The autopsies showed lesions of pure hog cholera or alterations due to a mixed infection of hog cholera and of pasteurellosis.

Notes on Chrysopa dorsalis, E. Maude Alderson (Ent. Mo. Mag., 2. ser., 22 (1911), No. 255, pp. 49-54, pl. 1, fig. 1).—An account of the life history and habits of this insect.

Gipsy and brown-tail moth suppression, F. W. Rane (Ann. Rpt. State Forcer Mass., 7 (1910), pp. 65-115, pls. 7, map 1).—The details of eradication work conducted by the State in 1910 are here reported.

During the year many improvements were made in spraying apparatus and methods, it being found possible for a gang to thoroughly spray as many as 23½ acres of heavy growth in one day. In experiments conducted newly hatched larvae were caught on tanglefoot and screens at distances varying from 50 to 600 feet, and a single caterpillar upon one screen on May 11 which was 1.833 feet from the point of liberation. These experiments demonstrated conclusively that small caterpillars of the gipsy moth may be carried by wind. This method of distribution is probably most frequent when the caterpillars are in the first, or possibly in the second stage, at which time they spin large quantities of silk for the purpose of lowering themselves from the trees or foliage. It is probable that these insects are often carried long distances in this way, and
that large numbers of them perish every year because they fail to come in contact with suitable food.”

Reports by L. O. Howard on Parasite Work (pp. 94-98); by A. T. Speare on The Fungus Diseases of the Brown-tail and the Gipsy Moths (pp. 98-101); and by H. N. Jones on Further Studies on the Nature of the Wilt Disease of the Gipsy Moth Larvae (pp. 101-105) are also included.

Spraying for codling moth in Galloway orchard (Oreg. Agr. Col. Bul., 1. ser., 1911. No. 48, pp. 56, 58).—Tests made of the comparative value of 1, 2, and 3 applications of lead arsenate 1.5:50 are summarized in the following table:

*Comparative tests of one, two, and three applications of lead arsenate for codling moth.*

Spraying for the codling moth (Oreg. Agr. Col. Bul., 1. ser., 1911, No. 48, pp. 29, 31).—The results of tests made to determine the relative value of one and two sprays in controlling the codling moth, in which 12-year-old trees were sprayed with arsenate of lead 1:50, are summarized in the following table:

*Comparative tests of one and two applications of lead arsenate for codling moth.*

History of spraying in the Pajaro Valley, C. W. Woodworth (Better Fruit, 5 (1911), No. 10, pp. 65-70, fig. 1).—Much of the data here presented have been previously noted from another source (E. S. R., 24, p. 560). In regard to zinc arsenate the author states that it has proved to be the safest of the arsenicals that can be procured in the form of dry powder, though not as safe as neutral lead arsenate. It is said to have been used without very serious evidence of burning in orchards where dusting has been adopted instead of spraying.

Solving the problem of the codling moth, E. P. Taylor (Better Fruit, 5 (1911), No. 10, pp. 77-80).—The author considers the unusually large percentage of wormy fruit in the Grand Valley of Colorado in 1910 to have been due to the comparatively light crop of fruit and the superabundance of worms that hibernated successfully as a result of favorable climatic conditions. In 2 unsprayed orchards examined on June 18, 97.2 per cent of the apples still upon the trees in a Ben Davis orchard and 96.6 per cent in a Winesap orchard were already wormy. In a third unsprayed orchard examined on July 1, 96.8 per cent of the fruit still upon the trees were wormy.

The author again (E. S. R., 18, p. 951) calls attention to the fact that the number of sprays required to control the moth in an orchard will depend principally upon (1) previous infestation of the orchard, (2) proximity to
other infested orchards. (3) efficiency of earlier sprays, and (4) the variety of fruit. He considers it folly for anyone to state arbitrarily the exact number of sprays necessary under all conditions to control the codling moth.

Maize stalk borer, Sesamia fusca, C. W. Mally (Agr. Jour. Cape Good Hope, 37 (1910), No. 6, pp. 686, 687).—Notes on the migratory habits of the larve are given.

Investigations on the cochylis and eudemis moths (Rev. Vit., 35 (1911), No. 894, pp. 113-156, pl. 1, figs. 17).—Papers are here presented on the differential biological characteristics of Cochylis ambiguella and Eudemis botrana, and their geographical distribution, by J. Feytaud; methods of combating them, by J. Vincens; the destruction of adult moths in Champagne, by P. Dépulset; preventive treatment in large vineyards, by J. Capus and J. Feytaud; the use of insecticides against the cochylis, by L. Moreau and E. Vinet; the occurrence of these moths in the various Provinces of France; and general conclusions by R. Brunet.

New treatment of the vine cochylis, Catoni (Feuille Inform. Min. Agr. [Paris], 1910, No. 37; abs. in Internatl. Inst. Agr. [Rome], Bull. Bur. Agr. Intel. and Plant Diseases, 1910, Nov., p. 179).—An emulsion consisting of 0.5 kg. of carbon disulphid and 2 kg. of yellow soap in 100 liters of water has been found most efficacious in the destruction of the cochylis. The soap is first dissolved in hot water, the remainder of the 100 liters of water is added cold to the emulsion and the carbon disulphid then added while the mixture is emulsified. This emulsion will penetrate the flowers of the grape where the insect lies hidden.

Nyssomyzomyia rossi and malaria, C. A. Bentley (Paludism [Simla], 1911, No. 2, pp. 35-42).—From the observations here reported the author concludes that N. rossi is naturally refractory to malarial infection, but that this immunity may sometimes be broken down, notably under conditions inseparable from feeding experiments conducted with mosquitoes in captivity.

The seasonal malarial infection of Neocellia stephensi in Bombay, C. A. Bentley (Paludism [Simla], 1911, No. 2, pp. 43-51).—The author thinks that existing information justifies the conclusion that the infection of malaria-carrying anopheles both as regards zygotes and sporozoits is subject to seasonal variation, that this variation can not be explained on the ground of change of temperature alone, and that careful investigation into seasonal infection of anopheles is required.

[Notes on mosquitoes], S. P. James (Paludism [Simla], 1911, No. 2, pp. 52-88, pl. 1).—These notes include provisional lists, etc., of the anopheles known to occur in India, descriptions of a new anopheline and of a new genus and species of culicine, and an account of the development of the egg follicle in anopheles by S. K. Christophers.

Relation of the buffalo or other gnats in Texas to pellagra, F. W. Mally (Bull. Tex. Bd. Health, 4 (1910), No. 12, pp. 31-36).—The greater number of 250 replies received to a letter of inquiry sent out by the author to physicians in Texas show the majority of pellagra cases to be found in counties in which simulid gnats apparently do not occur. There seems to be a practical unanimity among the physicians who have treated pellagra cases that they can not trace any relationship to the agency of the buffalo gnat, even where found in their localities. The gnat-infested districts appear to be largely confined to northeast Texas and counties bordering the Sabine, Neches, and Trinity Rivers, thus being practically confined to the area of greatest rainfall in Texas, while the districts where the greatest number of cases of pellagra are found are in the areas of lesser rainfall to the west.
Experiments to ascertain if certain Tabanidæ act as the carriers of Trypanosoma pectorum, D. Bruce et al. (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. 565, pp. 349–358, pl. 1).—"Trypanosoma cuedens, T. thoracicus, and T. fuscomarginatus appeared to be unable to transmit T. pectorum from infected to healthy cattle by the mechanical method of transmission. Owing to the short life of these tabanids in captivity it is impossible, from the above experiments, to state whether they can convey the disease (T. pectorum) after a period of development of the trypanosome in the fly. We believe the three types of flagellates found in T. cuedens and T. thoracicus to be various stages in the development of a harmless Crithidium in these flies."

Experiments to ascertain if Trypanosoma gambiense during its development within Glossina palpalis is infective, D. Bruce et al. (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. 565, pp. 345–348).—"Trypanosoma gambiense may retain their virulence, as ascertained by direct inoculation into susceptible animals, for a period of 2 days after they are ingested by G. palpalis. After the trypanosomes have been within the gut of the fly for 2 days the power of infecting animals with sleeping sickness, when inoculated subsequently, is lost for a period of 22 days. T. gambiense regains the power of infecting by direct inoculation after it has been about 24 days within the intestine of the fly. The number of days during which the virulence of the trypanosomes contained in the fly is lost roughly coincides with the time that the infected fly is incapable of transmitting sleeping sickness by biting susceptible animals. There is some evidence that the salivary glands of the fly are invaded by virulent forms of the parasite 36 days after the fly has fed upon infected blood."

Experiments to investigate the infectivity of Glossina palpalis fed on sleeping sickness patients under treatment, D. Bruce et al. (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. 565, pp. 338–344).—It was found that Glossina palpalis fed on natives suffering from sleeping sickness, whether untreated by drugs or treated by arsenic and other drugs, may become infected and be capable of transferring the disease to healthy animals.

Remarks on the egg-laying of Stomoxys calcitrans and rearing the larvae of Muscidae, M. Langéron (Compt. Rend. Soc. Biol. [Paris], 69 (1910), No. 28, pp. 230, 231; abs. in Jour. Trop. Vet. Sci., 6 (1911), No. 1, pp. 60, 61).—The author finds that boiled bran forms a very good medium for the development of the larvæ of the Muscidae. It must be kept moist and the light excluded.

Third report on flies as carriers of infection (Rpts. Local Govt. Bd. [Gr. Brit.], Pub. Health and Med. Subjs., n. ser., 1910, No. 30, pp. 48, pls. 7, figs. 3).—Three papers are here presented, namely, Observations on the Ways in which Artificially-infected Flies (Musca domestica) Carry and Distribute Pathogenic and other Bacteria, by G. S. Graham-Smith (pp. 1–40); Summary of Literature Relating to the Bionomics of the Parasitic Fungus of Flies, Empisola musca, with Special Reference to the Economic Aspect, by J. Bernstein (pp. 41–45); and Note as to Work in Hand, but not yet Published, and as to Proposed Further Work in Reference to Flies as Carriers of Infection, by S. M. Copeman (pp. 45–48).

The experiments conducted by Graham-Smith show that nonspore-bearing bacterin frequently survive for several days in the crops of flies and that after a meal flies may regurgitate some of the contents of their crops through the proboscis. "A fly which has access to abundant food produces between 15 and 30 deposits (vomits and feces) in 24 hours ... Experiments with Bacillus prodigiosus show that flies may infect sugar 48 hours after feeding on infected material, and that clean flies may infect themselves by feeding on the recent deposits of infected flies. In the few experiments which were tried, milk and
ment were not infected. Flies fed on anthrax spores did, however, infect the sirup which was given to them as food."

Notes on fruit flies (Tryptetidae) with descriptions of new species, W. W. Froeggatt (Proc. Linn. Soc. N. S. Wales, 35 (1910), pt. 4, pp. 862-872).—In this paper the author presents further information upon fruit flies (E. S. R., 22, p. 550). Seven species are described as new to science, namely, a mistletoe fruit fly (Ceratitis toranithi), bred from fruits of Loranthus pendulus on Eucalyptus sp. in West Australia; Dacus kingii, bred from the fruits of the usher tree (Calatropsis procera) in Khartum; D. pepisata from the Russell Group of Solomon Islands; D. passiforae, bred from Granadilla fruits and mangoes, New Zealand; D. tonyensis, bred from mangoes imported into New Zealand; D. raro-tonga, bred from mangoes in Raratonga, Cook Islands; and D. kirkii, bred from peaches and from island fruit imported into New Zealand.

The French bean fly, Agromyza phaseoli, W. W. Froeggatt (Agr. Gaz. N. S. Wales, 22 (1911), No. 2, pp. 151-154, pl. 1).—An account is given of the life history and remedial measures for this leaf-mining fly, which, though apparently a native of Australia, was not recorded until 1908, in which year it injured bean plants in the vicinity of Eureka and Wamberal. It was the source of serious injury in 1910, having spread over a much larger area than that occupied in former years.

The danger of transporting plague long distances through the intermediation of the flea, A. Raybaud (Presse Méd. [Paris], 1911, No. 19, pp. 179, 180; abs. Jour. Am. Med. Assoc., 56 (1911), No. 15, pl. 2, p. 1152).—The author calls attention to the fact that since plague germs may remain virulent in the rat flea (CeratophyUus fasciatus) during hibernation for a period of from 1 month to 45 days, the disease may be conveyed long distances in this manner. He suggests that when the fleas leave the bodies of animals which have succumbed to plague they may seek refuge in bales of goods or cracks of boxes and live there at a temperature which renders them torpid, practically hibernating, while the plague germs maintain their vitality and virulence.

Researches on the Ascaridæ of Carnivora, A. Kaillet and A. Henry (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 1, pp. 12-15).—The authors recognize 2 genera of ascarids that are parasitic in Carnivora, namely, Belascaris and Toxascaris, both of which were described by Leiper in 1907. Five species are described as belonging to the former genus Belascaris and three to the latter. B. mystax is parasitic in the cat and other Felidae and B. marginata and T. limbata n. sp. in the dog.

Technical papers on miscellaneous forest insects, III.—A revision of the powder-post beetles of the family Lycidae of the United States and Europe, E. J. Kraus (U. S. Dept. Agr., Bur. Ent. Bul. 29, tech. ser., pt. 3, pp. 111-138).—In this paper the author points out the more prominent specific characters and gives the range of variation within the species. Following a brief introduction he deals with the history of the family Lycidae and the three genera recognized as belonging to it (Lycus, Lyctoxyylon, and Minthea), the principal characters of the family, synopsis of the genera, revisional notes, and synopsis of species of the genus Lycus. Systematic notes are given on 14 species of Lycus, of which one, L. politus, reared from licorice at Washington, D. C., is described as new, also on one species of Lyctoxyylon and 2 species of Minthea. A bibliography of 61 titles is included.

In an appendix (pp. 130-138) A. D. Hopkins presents notes on habits and distribution and a list of the described species of this family, 39 species of Lycus, 2 of Lyctoxyylon, and 2 of Minthea being listed.

"So far as known, the species of the family Lycidae live in dead and dry wood of natural growth, in the seasoned sapwood of commercial products,
and in the pith of vines and the dried roots of herbaceous plants, but do not infest the wood of coniferous trees. Some of the species appear to prefer the dead and dry wood of standing trees, shrubs, and vines under natural conditions, and therefore are rarely found in the commercial articles; for this reason they are not subject to temporary or permanent removal from the natural range of the species. The other species, which infest commercial products, are subject to wide distribution over the world."

A new species of Eccoptogaster, J. M. Swaine (Canad. Ent., 42 (1910), No. 2, pp. 33-35, pl. 1).—Eccoptogaster picea n. sp., collected at Hudson, Quebec, in branches of Picea canadensis, is reported to be the first species of this genus of beetles recorded from conifers in eastern North America.

The unknown snout beetle or bud weevil, G. Chase (Better Fruit, 5 (1911), No. 10, pp. 93, 94).—The author reports that in March, 1910, an undetermined species of weevil, which he had first observed in 1909 attacked all of the trees in an orchard of over 16,000 at Prosser, Wash. Good results were obtained from the application of kerosene emulsion in early March to the soil about the trees, where the weevils gathered in numbers varying from 12 to 50 to a tree. Thus far the author has found this weevil only on 1-year-old trees in soil that had been cleared from sagebrush two years previous.

The apple blossom weevil, N. Jachontoff (Izv Moskov, Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 16 (1910), No. 3, pp. 229-254, figs. 5, dgm. 1).—The author reviews the literature relating to the natural history of Anthonomus pomorum, records observations made personally in the gardens of the Moscow government and of the Moscow Agricultural Institute, and discusses remedial measures.

In 1909 weevils that mated on April 22 oviposited from May 11 to 16; the first nymphs appeared May 31 and the first adults on June 15. The species is quite widely distributed in Russia, especially in the southern and central parts of the country, where the injury caused by the larvae to the flower buds sometimes rises as high as from 50 to 75 per cent.

A bibliography of 42 titles is appended.

The occurrence of bee diseases in the United States, E. F. Phillips (U. S. Dept. Agr., Bur. Ent. Circ. 138, pp. 25).—In this preliminary report the information at hand on the occurrence of American and European foul brood in this country is listed by States and counties. Although most of the data were obtained by correspondence, the records are based on examinations made in the bacteriological laboratory of the Bureau, in all 1,800 samples having been examined. The counties from which satisfactory samples have not been received but from which information of the presence of the disease has been received from an apiary inspector or beekeeper thought to be conversant with the disease are listed as "suspected." Foul brood is known to occur in 415 of the 2,932 counties, American foul brood occurring in 294 and European foul brood in 165.

For the information of beekeepers a brief statement is made concerning the apiary inspection in each State where it is provided by law.

A supposed occurrence of Anagrus incarnatus in the United States, A. A. Girault (Ent. News, 22 (1911), No. 5, pp. 207-210).—The species A. spiritus, here described as new to science, is supposed to have been reared from the apple aphis.

Compressed air spraying, J. W. Stewart (Amer. Agr., 87 (1911), No. 17, p. 656, fig. 1).—The author, who has used compressed air in large orchards in Berkeley County, W. Va., during a period of five years, here discusses its advantages and disadvantages. While not recommended for use in orchards that are not of sufficient size to warrant an expenditure of $1,000 for spraying outfits, he considers the compressed air equipment to be a necessity in large orchards.
FOODS—HUMAN NUTRITION.

Foods and their adulteration, H. W. Wiley (Philadelphia, 1911, 2 ed., rev. and enl., pp. XIII+641, pls. 11. figs. 87).—The author states that the text of this handbook (E. S. R., 18, p. 1064) has been revised and statistical matter brought up to date. The regulations for inspection and the rules and regulations for the enforcement of the food and drugs act have been omitted and the space thus saved has been devoted to the expansion of the article on infants' and invalids' food and to a new section given to simple tests, such as may be practiced with some degree of success in the household, for detecting ordinary adulterations.

The section on infants' and invalids' foods discusses such questions as infant dietetics and substitutes for mother's milk, sour milk and longevity, meat extracts and other meat preparations, diet in obesity and tuberculosis, and other questions of invalid dietetics, and gives a compilation of analyses of infants' and invalids' foods, particularly proprietary articles and commercial products.

The meat industry and meat inspections, G. R. Leighton and L. M. Douglas (London, 1910, vols. 1, pp. XVI+332, pls. 10, figs. 246, dysms. 3, chart 1; 2, pp. VIII+335–735, pls. 10, figs. 331, dysms. 48; 3, pp. VIII+737–1088, pls. 26, figs. 195, dysms. 2; 4, pp. VII+1089–1412, pls. 5, figs. 29, dysms. 3; 5, pp. VII+1413–1720, pls. 6, figs. 93, dysms. 2).—This series of volumes is designed to give a comprehensive account of the domestic animals, game, poultry, and fish supplied to the British meat market, together with a description of the industrial processes connected with the meat industry and the scientific inspection of meat.

The first volume is concerned with the breeding and feeding of domestic animals, bacon and ham curing, fish and fish markets, the handling and inspection of fish, and similar topics, while the second volume has to do with abattoirs, the meat trade, refrigeration, the handling of meats, the chemistry and cooking of meat, the relative value of fresh and cold storage meat, the pickling of meat, and related topics. The remaining volumes are devoted to questions of slaughtering, meat inspection, and other such topics.

Edible frogs, I. H. Burkill (Agr. Ledger, 1911, No. 2 (Anim. Prod. Ser., No. 4), pp. 11–15).—Descriptive data are given regarding frogs used as food in India.

The influence of the combined harvester on the value of the wheat, R. Stewart and C. T. Hirst (Utah Sta. Bul. 113, pp. 165–177, figs. 3).—Owing to the belief that wheat harvested with the combined harvester yields grain of inferior quality, the matter was studied by comparing Turkey and Kofod wheats thus harvested with samples cut with a binder and stacked for six weeks before thrashing.

As shown by data collected regarding the yield of milling products, the composition of the wheat, flour, bran, and shorts, and the bread-making quality of the flour, no differences were observed which could be attributed to the method of harvesting. From the recorded data it was apparent that the Turkey Red wheat was distinctly superior to the Kofod for bread-making purposes, and the authors are of the opinion that since the complaints have been greatest from the sections where the Kofod wheat is largely grown, the obvious remedy is to grow Turkey wheat, as this gives a larger crop and a better yield of flour, which is richer in protein, absorbs the greater amount of water, and makes a loaf of greater volume.

Keeping qualities of wrapped and unwrapped bread, H. E. Barnard (Bakers' Helper, 24 (1910), No. 280, pp. 738, 739).—Studies are reported of the keeping quality of bread of different kinds wrapped in paraffin paper and in ordinary porous paper.
In general, the ordinary loaf when wrapped in paraffin paper remained in good condition for three or four, and in some cases for five days, while the unwrapped loaf became dry and stale at the end of two days. Loaves wrapped in porous paper dried out more rapidly but showed less tendency to become sour. Vienna bread and rye loaf bread lost their natural characteristics rapidly when wrapped, since the moisture in the center became evenly distributed throughout the loaf, thus destroying the flavor and texture of the crust. It was also found that after four or five days the ordinary wrapped loaf became unpalatable, through an increase of acidity, and furthermore, that such bread would eventually mold.

As a whole, the author believes that the experimental evidence is in favor of wrapping bread, "and since the ordinary unwrapped loaf is now considered unsalable at the end of the second day, the use of the wrapper at least doubles the period during which it is merchantable."

Tests of bread wrapping, C. A. A. Utt (Bul, Bd. Health, 7, (1911), No. 3, pp. 52-60).—In tests reported in continuation of work noted above different kinds of bread were kept for four or five days. In general, the unwrapped loaf lost about twice as much moisture as the wrapped loaf, while the acidity remained practically the same. The wrapped bread was in edible condition for twice its ordinary period.

"Leaving out the purely sanitary reasons, which after all are the greatest, for wrapping bread, our results, if properly interpreted, can only argue in its favor.

"If bread is only warm when wrapped it keeps better; it does not get moldy; the acidity does not increase any more for the wrapped than the unwrapped loaf; the crust softens, but does not get tough; it does not injure the flavor; the moisture becomes uniformly distributed, resulting in a much better loaf."

Letters received from Kansas bakers in reply to a circular inquiry showed that those "who have tried bread wrapping favor it, and that their sales have increased. The opposition displayed in many letters is evidently due to ignorance."

The digestibility of vegetables in health and disease and the effect of the stomach in disintegrating vegetable materials, A. Schmidt (Deut. Med. Wochenschr., 37 (1911), No. 10, pp. 485-488; Jour, Amer. Med. Assoc., 56 (1911); No. 15, p. 1154).—On the basis of his own studies and those of other investigators, the author discusses the digestibility of raw and cooked vegetables, particularly the effect of the stomach upon the digestion of such materials. His general conclusion is that the pepsin-hydrochloric acid, when the action is continued for a sufficient time, causes the vegetable substances to swell and soften in such a way that they may be acted upon subsequently by gastric juice.

The author was unable to discover any evidence to sustain the assumption that the digestion of vegetables occurs chiefly in the intestines and that it is due mainly to the work of microbes.

Changes in the constituents of peas soaked and cooked in water and in solutions of sugar and salt, E. Poppe (Bul, Soc. Chim. Belg., 25 (1911), No. 3, pp. 136-135).—In the experiments reported dried peas were soaked for varying lengths of time in distilled water and in saturated, one-half saturated, and one-fourth saturated solutions of common salt and of sugar, at different degrees of temperature, with a view to determining the amount of nitrogenous material, phosphates, chlorin, and carbohydrates removed.

It was found that the loss of nitrogen was greatest with distilled water and least with the saturated solution of salt, and that in general a high temperature favored extraction of nitrogenous substances and phosphates. The
largest amount of chlorin was extracted with water at a temperature of 100° C. Distilled water at 100° C, removed some carbohydrates from the peas, but this was not the case with the saline solution. In general, the amount of material extracted seemed to depend on the concentration of the solutions rather than on the temperature.

Both the concentration and the temperature influenced the amount of the solution absorbed by the peas. The author believes that the variations observed are due to differences in the properties of living cells as contrasted with those in which protoplasm has been destroyed.

Some investigations concerning the keeping qualities of sugar sirups, fruit sirups, and crushed fruits, H. E. Barnard and L. L. Miller (Ann. Rpt. Bd. Health Ind., 28 (1909), pp. 331-352, charts 8).—In this investigation 286 samples of crushed fruits, fruit sirups, sugar sirups, and concentrates were studied with special reference to factors affecting keeping quality in their commercial use in the soda-water trade.

According to the authors' conclusions, the results obtained indicate that concentrated crushed fruits and fruit sirups such as are marketed in tins, etc., may be kept without loss for from one to three months after opening when kept at a temperature below 50° F., and that soda-water-fountain sirups made up with 14-pound sugar sirup will keep from two to four weeks without the slightest evidence of fermentation. They conclude further "that crushed fruit concentrates diluted with sugar sirup of 14 pounds to the gallon strength will keep when exposed at room temperature from three to ten days, and when goods are placed in the refrigerator of the fountain during the nighttime for a period of eight hours, the time during which they keep in good condition is nearly doubled." "The keeping quality of crushed fruit and fruit sirups is influenced materially by the concentration of the sugar solution used as diluents. While in most instances a 10-pound sirup is sufficient to hold the goods for a period long enough to allow of their disposal, yet concentrates which are from 12 to 16 pounds materially improve the keeping qualities of the goods. From our experiments it appears that a 14-pound solution is best adapted for use, although a saturated sugar sirup which contains about 16 pounds to the gallon of water can always be employed with good results."

The authors also conclude from their investigations that sugar sirup may be best prepared by dissolving the sugar in hot water. "If tap water or unsterilized water is used, the sirup should be brought to 100° C. While sugar sirups made up in the cold are in most cases satisfactory, yet it is evident that they may contain mold spores, which injure the keeping quality of the preparation."

The occurrence of micro-organisms in the interior of meat, potatoes, and sausage, E. Maurel (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 7, pp. 241-244).—In all the samples examined the author found a diplococcus.

[Food analyses], H. H. Mann (Ann. Rpt. Dept. Agr. Bombay, 1909-10, pp. 46-58).—A number of foodstuffs were examined. The author reports the composition of banana or plantain flour. Though a considerable amount of this could be produced, he states that as yet it has not been possible to find a market for it.

Quantitative aspects of nutrition, H. C. Sherman (Teachers Col. [N. Y.] Bul., 2. ser., 1911, No. 15, pp. 16).—Factors which affect food requirements, the characteristics of different nutrients, including mineral constituents, and similar questions are considered in this useful summary of the subject, particularly in its quantitative relations.

The feeding of young children, Mary S. Rose (Teachers Col. [N. Y.] Bul., 2. ser., 1911, No. 10, pp. 10).—This pamphlet, which gives practical directions as
well as general information, was prepared especially for the committee on foods and feeding of the Child Welfare Exhibit, New York, 1911.

Experiments on the effects of animal protein on vegetarians, P. Albertoni and F. Rossi (Arch. Expt. Path. u. Pharmakol., 61 (1911), No. 5-6, pp. 439-455).—Continuing experiments previously reported (E. S. R., 20, p. 965), the authors carried on tests in which meat (at first 100 gm. and later 200 gm.) and eggs (at first two and later four) were added to the daily food of persons accustomed to a strict vegetarian diet. In the experiments with meat, the usual diet supplied on an average, in round numbers, 75 gm. protein per day, the diet with a small amount of meat 98 gm., and that with a larger amount 118 gm., the energy values being, in round numbers, 3,035, 3,283, and 3,331 calories, respectively. In the experiments with eggs, the usual diet supplied, in round numbers, 67 gm. protein, the diet with two eggs 79 gm., and that with four eggs 83 gm., the energy values being 2,686, 3,006, and 2,890 calories, respectively. The balance of income and outgo of nitrogen and phosphorus was determined and dynamometer tests were made.

The authors state that the addition of animal food to the diet influenced favorably the work of the intestines and led to a gain in nitrogen and to gains in body weight. The individuals also gained in strength and in the hemoglobin content of the blood. These results, like those obtained in their earlier experiments, they attribute to the increased protein metabolism, and especially to the addition of animal protein to the diet.

In their general discussion they point out that many persons undoubtedly eat too much and others too little. On the whole, they believe that while it is possible to maintain life on from 40 to 50 gm. protein a day, yet they do not think that on such a diet man is in better condition for the production of energy, and they consider that an abundance of protein, especially of animal origin, has a favorable effect.

Discussion on food requirements for sustenance and work, C. H. Melville (Brit. Med. Jour., 1910, No. 2600, pp. 1337-1341).—The test reported was made with 20 infantry soldiers from 18 to 38 years of age and weighing on an average 64.15 kg. On six consecutive days they marched on an average from 12 to 13 miles, carrying a load of 54 lbs. (24.55 kg.). Then after a day's rest the marching was continued for five more days.

According to the author's calculations, the work was equivalent to 1,034 calories per day, or to approximately 90 calories per mile of ordinary road. He estimates further that the internal muscular work and the external muscular work during nonmarching hours were equivalent to 3,000 calories, which would make the total work 4,034 calories per day.

The food consisted of bread, meat, potatoes, jam, and sugar, with tea, condiments, etc. During the first week the diet supplied 190 gm. protein and 3,426 calories per man per day, and during the remainder of the time 145 gm. protein and 3,503 calories. The average for the whole period was 168 gm. protein, 84 gm. fat, and 480 gm. carbohydrates per day, the energy value being 3,481 calories.

During the first three days of the test there was an average gain of 0.55 kg. in weight, followed by a period of two days during which the weight remained stationary. After this, with the exception of a slight rise on the day following the day of rest, the weight diminished steadily until the end of the experiment, the average decrease being 1 kg. for the whole period. The officers accompanying the party were restricted in their diet in the same way as the men, and similar changes were noticed in their body weight. The increase in weight at the beginning of the period is due, in the author's opinion, to retention of water in the system. In discussing changes in body weight, the author calculates
that the daily loss was represented by about 60 gm. of body fat and 170 gm. of flesh.

The author states that during the period the weather was very bad, and the men were subjected to the hardships of camp life in bad weather.

As regards the adequacy of the diet, he considers the energy value somewhat too low, since it was smaller than the calculated energy expenditure. He considers that the protein supply during the first week was certainly ample, and possibly larger than was necessary, and that the substitution of some fat for part of the protein would have been an advantage. He believes that the average amount, 145 gm. per day, supplied in the form of fresh meat and bread, was as low "as it is advisable to go, and might well be increased, especially when hard work is demanded of men under conditions of exposure."

The paper was followed by a discussion, in which R. Hutchison, among others, participated. He agreed with the author "that the protein ration was none too high, for whatever views one might hold as to the protein requirements of the body, all careful investigations had shown that there was an instinctive consumption of large quantities when hard muscular work had to be done."

The influence of the preceding diet on the respiratory quotient after active digestion has ceased, F. G. Benedict, L. E. Emies, and J. A. Rich (Amer. Jour. Physiol., 27 (1911), No. 4, pp. 383-405).—Both the small respiration apparatus and the respiration calorimeter of the Carnegie Nutrition Research Laboratory were used in the experiments reported, which were made with a number of subjects, diets both rich and poor in carbohydrates being compared.

In general, the conclusion was drawn that the respiratory quotient determined 12 hours after a meal rich in carbohydrates was higher than when the last meal contained only a small amount of carbohydrates. The possibility of this high respiratory quotient being due to the delayed absorption and combustion of carbohydrates in the alimentary tract is discussed, but the authors believe that the evidence is rather against the theory.

"Obviously the previous body condition plays a very important rôle. The extent to which the body storage of glycogen has been drawn upon, the muscular activity of the day previous to the experiment, possibly the temperature of the surrounding air, the general diet of the individual for several days before—in fact, anything which contributes to a disturbance of the storage of glycogen in the body—may alter the influence of the ingestion of a carbohydrate-rich meal. If the glycogen storage in the body is at a low point, the ingestion of a carbohydrate-rich meal does not result in an increased respiratory quotient in accordance with the amount ingested, as a not inconsiderable proportion of the carbohydrate may be stored immediately as glycogen. Until this glycogen storage has been replenished the combustion of carbohydrate in the food may be delayed. On the other hand, with individuals subsisting without food and remaining quiet in a respiration chamber, the store of glycogen may last for some time. From these data we may infer, then, that muscular activity may play an important rôle in affecting the storage of glycogen."

Other questions which have to do with the general subject are discussed.

Fasting studies.—III. Nitrogen partition of 2 men through 7-day fasts following the prolonged ingestion of a low protein diet; supplemented by comparative data from the subsequent feeding period, P. E. Howe, H. A. Mattill, and P. B. Hawk (Jour, Amer. Chem. Soc., 33 (1911), No. 4, pp. 585-598).—One of the subjects included in this investigation had been living for a long time on a low protein diet containing meat, and the other on a low proteid nonflesh diet. The fasting period covered 7 days during which the subjects received daily a constant quantity of water.
Some of the authors’ conclusions follow:

“With both subjects the excretion of total nitrogen during the fast remained above the plane of the normal preliminary feeding period, with the exception of the first day of fasting. This unique finding we have interpreted as being due to the fact that the subjects began the fast from a low protein plane. In spite of this unusual condition as regards nitrogen output, however, the nitrogen excretion on the seventh day was very close to that for the seventh day of fasting men as determined by other investigators, i.e., 10 gm.

“The largest water ingestion was not followed by the most complete elimination by the kidneys. A subject ingesting 1,750 cc. per day eliminated 12 to 35 per cent less than a subject ingesting only 1,500 cc. per day.

“[There was] a decrease in body weight, aggregating 7.44 per cent for one subject and 7.62 per cent for the other subject.

“No discomfort [was noted] with the exception of a slight feeling of hunger on the first or second day.”

When food was taken subsequent to the fasting, it was accompanied by “a marked retention of water during the first two days, and a pronounced retention of nitrogen from the second to the sixth day inclusive.”

On the fourth day there was a return to normal nitrogen metabolism as indicated by the nitrogen partition. “This return to the normal was preceded by an extremely excessive output of ammonia upon the third day. The return to the normal we have interpreted as having been brought about simply through the ingestion of nutritive material, the character of the diet having no important bearing.

“It was necessary to place the subjects upon a higher nutritive plane after the fast than before the fast in order to maintain body weight and nitrogen equilibrium.”

The stimulation of gastric secretion under the influence of water drinking with meals, F. Wills and P. B. Hawk (Abs. in Jour. Biol. Chem., 9 (1911), No. 2, pp. XXIX, XXX; Proc. Amer. Soc. Biol. Chem., 2 (1910), No. 1, pp. 23, 24)—Two men brought to a condition of nitrogen equilibrium on a diet with a low water content were given at meal time extra volumes of water, ranging from 1,500 to 4,000 cc.

“During the periods of increased water ingestion there was in each instance an increase in the ammonia excretion which was directly proportional to the extra volume of water ingested. This finding was interpreted as indicating that the water ingestion had stimulated the flow of gastric juice, thus causing the production of a greater quantity of hydrochloric acid than could be neutralized by the customary means. . . . If we calculate the increased ammonia excretion, on the basis of a 100 cc. increase in the water ingestion we find that the excretion was a trifle higher during moderate water drinking than during copious water drinking. This would indicate that after a certain limit had been reached in water ingestion each succeeding 100 cc. of water was less efficient as a stimulating factor than were the 100 cc. portions ingested before the limit above mentioned had been reached.”

The utilization of ingested fat under the influence of copious and moderate water drinking with meals, H. A. Matill and P. B. Hawk (Abs. in Jour. Biol. Chem., 9 (1911), No. 2, p. XX; Proc. Amer. Soc. Biol. Chem., 2 (1910), No. 1, p. 11).—Experiments were made with man on a uniform diet, a period in which large amounts of water were taken being preceded and followed by a period in which smaller amounts of water were ingested.

“When 1 liter of water was taken with each meal, the average daily excretion of fat was much reduced, and a similar but less marked reduction was observed when 500 cc. of water was taken.
"The better digestion and absorption of fat was probably due to any or all of the following factors: (1) Increased secretion of gastric juice and, independently, of pancreatic juice; (2) increased acidity of the chyme bringing about more active secretion of pancreatic juice and bile; (3) increased peristalsis due to larger volume of material in the intestine; (4) increased blood pressure due to rapidly absorbed water; (5) more complete hydrolysis by lipase because of increased dilution."

The effects of various forms of exercise on systolic, diastolic, and pulse pressures and pulse rate, O. S. Lowesley (Amerr. Jour. Physiol., 27 (1911), No. 5, pp. 446-466, anaus. 5).—In the investigations reported the author has studied the effect on the heart of different kinds of exercise.

Quotations from his conclusions follow:

"Pulse rate, which always increases during exercise, decreases rapidly after its completion. This drop in the curve of the pulse rate is frequently followed by a secondary rise which is possibly a reflex effect due to the low blood pressure of the subnormal stage. In no case was it observed that this secondary rise was accompanied by a rise in blood pressure.

"Rapid exercises (vigorous, fatiguing, and exhausting) are followed by a full of pressure below normal which lasts longer than after moderate exercise, even if the former is continued for a very short period and the latter for quite a long period of time. If we consider the subnormal phase as indicative of an overstrain following upon the great reflex excitation of the heart and vasomotor center, then it would seem that after these so-called rapid exercises the strain is more serious, as is shown by the much longer time required before the conditions return to their normal level.

"If our interpretation of the subnormal phase is correct, it would follow that the so-called field events, consisting of jumping, shot putting, discus and hammer throwing, and baseball, gymnastium apparatus work, and exercises of a similar nature, are preferable to rapid exercises, such as basket ball, football, and running races. This is particularly true in the case of the rapidly growing youth, whose heart is under the additional demand of keeping pace with an increase in the tissue mass of the body.

"There is less strain put upon the circulatory system by walking a number of miles at a moderate rate than by sprinting 100 yards at top speed. This conclusion follows from the fact that blood pressure returns to normal after moderate exercise in about 30 minutes, while after short sprints the subnormal stage continues about three times as long.

"Long-distance running races and similar forms of exhaustive exercise give rise to a serious strain on the heart, as is indicated by the long period of subnormal blood pressure.

"It would seem probable that in individual cases the beneficial or injurious effect of any given form or amount of exercise might be determined by observations upon the subnormal phase following the exercise. When the subnormal phase returns to normal within 60 minutes, the exercise may be considered as lying well within hygienic limits for that individual, while a return that is delayed beyond 120 minutes may be regarded as exceeding these limits."

Law of the body expenditure following work, J. Amar (Compt. Rend. Acad. Sci. [Paris], 151 (1910), No. 21, pp. 952-954).—The author has studied the rate of recovery after exercise in experiments with man. The exercise was performed on a bicycle ergometer, and the respiratory exchange was determined. He believed that the oxygen consumption may be regarded as a measure of the body expenditure and that the changes after work should follow Newton's laws for cooling bodies, but, as was shown by experimental evidence, such was not the case.
The man-machine—the remarkable perfection of the human system as a mechanism, J. B. Huber (Sci. Amer., 10:1 (1911), No. 3, pp. 60, 72, figs. 1)—An illustrated description of apparatus and methods used in J. Amar's experiments noted on page 269.

Man's power—testing the energy expended by the human machine (Illus. London News [Amer. Ed.], 48 (1911), No. 1238, p. 107, figs. 2).—See page 269.

The respiratory exchange as affected by body position, L. E. Emmes and J. A. Riché (Amer. Jour. Physiol., 27 (1911), No. 4, pp. 406-413).—In general, the authors found that the pulse rate lying down was on an average 63, the carbon dioxide excretion 209 cc., and the oxygen consumption 236 cc. per minute. With a subject in a sitting position the pulse rate was 71, the carbon dioxide excretion 218 cc., and the oxygen consumption 254 cc. per minute.

"Inasmuch as the oxygen consumption is commonly considered as the best index of metabolism, it is seen that our experiments indicate an increase in metabolism amounting to 8 per cent" when the metabolism in the sitting position is compared with that when the subject is lying down.

In their discussion of the data reported the authors point out that for experimental purposes, when metabolism at a given condition of body rest is to be determined, it is of value to know. "as a result of experiments with the respiration apparatus, that the metabolism of a subject when sitting absolutely quiet in a chair, without extraneous muscular activity, represents a metabolism 8 per cent greater than that of a subject lying on a couch, with similar muscular rest. The difference in metabolism is then due, primarily, to the difference in the internal muscular activity necessitated by the sustaining of body parts. This is in conformity with the well-known fact that the pulse rate of an individual when sitting is always noticeably higher than when he is lying down. From these tests we could infer that if it were possible to so support the body of the subject in a sitting position that the pulse rate would be no greater than when the subject was lying down, the metabolism would be essentially the same in both positions."

Does lecithin influence growth? A. J. Goldfarb (Arch. Entwickl. Mech. Organ., 29 (1910), No. 2, pp. 255-274).—The author's conclusions, from a series of experiments with small animals (tadpoles and frogs, sea urchins' eggs, kittens, and guinea pigs), show that there is no clear evidence of growth stimulation as a result of the administration of lecithin.

The influence of cold baths on the glycogen content of man, G. LusS (Amer. Jour. Physiol., 27 (1911), No. 5, pp. 427-437).—The experiments reported were made with the aid of the small apparatus for studying the respiratory exchange devised by F. G. Benedict and previously noted (E. S. R., 21, p. 665).

The conclusions drawn by the author follow:

"Immersion of normal men in cold baths at a temperature of 10° when the intestine is free from carbohydrates induces shivering, which causes a rapid utilization of body glycogen, as determined by a fall in the respiratory quotient to the fasting level. In one very muscular individual this result could not be obtained.

"In one individual in whom the shivering had been severe, a quotient of 0.67 and another of 0.62 were found during subsequent periods of rest, which correspond to those observed during rest after a period of exhaustive exercise (glycogen formation from protein).

"The greatest increase in heat production which was brought about by the cold baths was 181 per cent above the normal. The urine remained free from albumin and from sugar."
On the question whether dextrose arises from cellulose in digestion, G. Lusk (Amer. Jour. Physiol., 27 (1911), No. 5, pp. 467, 468).—The author briefly summarizes data accumulated in connection with some of his earlier experiments, which support the contention that sugar does not arise from the digestion of cellulose.

Mucic acid and carbohydrate metabolism, L. B. Mendel and W. C. Rose (Abs. in Jour. Biol. Chem., 9 (1911), No. 2, p. XII; Proc. Amer. Soc. Biol. Chem., 2 (1910), No. 1, p. 6).—From experiments with animals the authors concludes "that mucic acid is presumably not an intermediary oxidative product in the metabolism of galactose or galactose-yielding carbohydrates. The urinary oxalic acid is only very slightly increased after the ingestion of large amounts of mucic acid. This increase is by no means as large as would be expected if mucic acid were a precursor of oxalic acid."

On creatinin metabolism, C. Voegtlin and Caroline B. Towles (Abs. in Jour. Biol. Chem., 9 (1911), No. 2, pp. XI, XII; Proc. Amer. Soc. Biol. Chem., 2 (1910), No. 1, pp. 5, 6).—From the data obtained with dogs and birds the conclusion is reached that the liver can hardly be supposed to occupy an important place in creatinin metabolism, as has been claimed by some investigators.

The sulphur balance in metabolism, A. E. Taylor (Abs. in Jour. Biol. Chem., 9 (1911), No. 2, pp. IX, X; Proc. Amer. Soc. Biol. Chem., 2 (1910), No. 1, pp. 3, 4).—The balance of income and outgo of sulphur was determined with six normal men for periods of nearly three months, with the object of ascertaining the relations of the sulphur balance. A condition of equilibrium was not observed, the output being regularly and notably higher than the intake. The author does not consider that the results obtained are trustworthy, the presumption being that errors were involved in the determinations of the sulphur index.

The nature of the chemical combinations of potassium in the tissues, W. Koch and C. C. Todd (Abs. in Jour. Biol. Chem., 9 (1911), No. 2, pp. XV, XVI; Proc. Amer. Soc. Biol. Chem., 2 (1910), No. 1, pp. 9, 10).—According to the authors, the results so far obtained indicate that "sodium and potassium phosphatid compounds exist in all the tissues of the body and are probably of much more importance than the hitherto assumed ion protein combination."

The elimination of caffeine in the bile, W. Salant and W. O. Emery (Proc. Soc. Expt. Biol. and Med., 7 (1910), No. 5, p. 155).—"The elimination of caffeine and its products of decomposition in the urine has been studied by a number of investigators in dogs, rabbits, and in man. Its presence in the digestive secretions has been recently made the subject of a special investigation in the pharmacological laboratory of the Bureau of Chemistry of [the Department of Agriculture]. It was found in the bile removed from the gall bladder of a number of dogs poisoned with caffeine. In every case appreciable quantities were found. A dog which was given 1.5 gm. of caffeine by mouth died four hours later. The bile removed from the gall bladder contained 4.4 mg. of caffeine. Similar results were obtained in other experiments. Experiments made on rabbits with temporary bile fistula have shown that the elimination of caffeine likewise takes place by this path in these animals. Caffeine was found in the bile two hours after its subcutaneous injection."

Chemical studies of human sweat, L. W. Riggs (Abs. in Jour. Biol. Chem., 9 (1911), No. 2, p. XIX; Proc. Amer. Soc. Biol. Chem., 2 (1910), No. 1, p. 13).—Forty-five samples were examined from persons in normal health and from nephritics. The total nitrogen, nitrogen as urea plus ammonia, inorganic solids, potassium, and chlorine were determined in the majority of the samples.
ANIMAL PRODUCTION.

Results of the examination of stock feeds, B. L. Purcell (Dept. Agr. and Immigr. Va., Dairy and Food Div. Bul. 14, 1910, pp. 118-152).—Analyses are reported of wheat bran and middlings, ship stuff, red dog flour, rye middlings, corn chop, cottonseed meal, corn bran, hominy feed, oil meal, gluten feed, malt sprouts, rice hulls, barley chaff, flax bran, peanut meal, and mixed feeds.

Fish guano and its use as feed, R. P. Skinner (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 103, p. 512).—Notes on the use, extent, and value of fish meal as feed for live stock are presented.

Report of animal husbandry, H. H. Simpson (New Mexico Sta. Rpt. 1910, pp. 32-36).—In a feeding test with steers the gains per head and day were as follows: On alfalfa 1.84 pounds at a cost of 3.92 cents per pound; on alfalfa and corn stover 1.17 pounds at a cost of 4.01 cents per pound; on alfalfa and corn meal 2.58 pounds at a cost of 7.33 cents per pound; and on alfalfa 60 days with corn as a supplement the last 30 days 2.06 pounds at a cost of 5.55 cents per pound.

Dairy cows kept on pasture and fed 6 pounds of grain per head and day, produced more milk than cows on the same pasture not fed grain, but the grain increased the cost per quart of milk by 0.82 cent.

Thirty-two pigs on alfalfa pasture made average daily gains per head as follows: Without supplement 0.254 pound, with 8 pounds of grain per day 0.657 pound, with 16 pounds of grain per day 0.73 pound, and with 64 pounds of skim milk per day 0.597 pound. The largest returns per acre for pasture were on the lots which were fed grain as a supplement.

Some methods of incubation of eggs were studied, with the following results: “It was found that by sprinkling the eggs during the last 3 days one-third more eggs were hatched, and the eggs that were sprinkled from the third day on gave about 10 per cent better hatch. Submerging the eggs did not seem to increase the hatch as much as sprinkling.

“While it is comparatively easy to develop the chicks in the large, thick-shelled, dark, Brahma eggs, it is very difficult to get a good hatch. From examination it was found that about 70 per cent of the large, heavy eggs that failed to hatch contained fully developed chicks.”

Bullock feeding experiment, G. B. Pinyon and B. N. Wale (Jour. Southeast Agr. Col. Wye, 1909, No. 18, pp. 21-23).—Molassclt gave better results in a steer-feeding experiment than in a similar experiment the preceding year.
(E. S. R., 23, p. 475), but heavy feeding with cottonseed and linseed cakes gave better results than either roots or molasses. The results of two years' work indicate that molasses may advantageously be used in place of roots for fattening bullocks in the proportion of 1 pound of molasses to 14 pounds of roots, where molasses is quoted at £5 per ton and roots valued on the farm at £7 6d. per ton.

There appeared to be but little difference in gains between the animals tied in stalls and those running loose in a covered yard.

**Resorption of fat.** P. F. Trowbridge (Science, n. scr., 33 (1911), No. 814, pp. 331, 332).—An abstract of a paper read before the American Association for the Advancement of Science, December, 1910.

"Seven calves six months old were fed for several months until in a well-fattened condition. One, thought to be the least fat, was slaughtered and analyzed as a check animal. The remaining animals were given the same kind of feed but varied in quantity. Two were held at a maintenance ration, two were so fed as to lose one-half pound per day, and the other two so as to gain one-half pound per day. At the end of 6 months one of each group was slaughtered and analyzed. The remaining submaintenance animal was slaughtered at the end of 11 months, and the remaining maintenance animal at the end of 12 months. The supermaintenance animal was not slaughtered, as the one-half pound per day gain at his age (2 years) was sufficient to make him improve in condition.

"All the maintenance and submaintenance animals lost in fat. The long-maintenance animal gained in total protein and also in flesh protein. All the animals gained in weight of skeleton from 9.5 to 16.6 per cent. The skeleton of all animals gained in protein, moisture, and ash, and in fat except in that of the long-submaintenance animal, which lost over 75 per cent of its original fat. The animal on long submaintenance (11 months) became greatly emaciated and the analysis showed that he had used up nearly all of his reserve store of fat, not only from his flesh, but from his skeleton. The short-submaintenance animal (6 months) and the long-maintenance animal (12 months) had used up nearly all the reserve fat of the tissues, but had not drawn upon the supply in the skeleton.

"The loss in moisture is not sufficient to correspond to the loss in protein for a lean meat or connective tissue, which supports the view that in certain stages, at least, of fat resorption the fat is in whole or in part replaced by water.

"The normal skeleton contains about 30 per cent moisture. In the long-submaintenance animal it has risen to 53 per cent, while the fat content of the skeleton has dropped from 16 per cent to 3 per cent. In this time the skeleton has gained nearly 1 per cent of its total weight in dry protein. The long-submaintenance animal lost 10,627 gm. in dry protein, but only 24,868 gm. in moisture, which lacks about 16,000 gm. of being enough to make up the protein loss to lean flesh and connective tissue. During this time the loss in fat was 43,829 gm., or about 90 per cent of the total fat present at the beginning."

**Cattle raising in Chiriqui.** F. Lindsay (Bul. Pan Amer. Union, 32 (1911), No. 4, pp. 643–651, figs. 3).—An account of the opportunities offered by certain districts of Panama for cattle raising on the public lands.

**Breeding from ewes at an early age.** B. N. Wale (Jour. Southeast, Agr. Col. Wyc, 1909, No. 18, pp. 28–31).—A first report of an experiment to ascertain to what extent breeding at 7 months instead of 1 year 7 months would reduce the size, vigor, and constitution of the ewes. For this purpose 50 crossbred Border Leicester and Cheviots were used. Half of the number were mated at 7 months. When producing and rearing a lamb, each ewe was dwarfed to the extent of 17 pounds as compared with the unmated ewes.
Comparative phosphatic manuring of swedes (Field Expts., Harper-Adams Agr. Col., and Staffordshire and Shropshire, Rpt. 1910, pp. 24–26).—In a comparison of basic slag and superphosphate as manures for swedes in respect to the feeding value of the roots, the value of the net gain in weight of sheep in 1910 in favor of the superphosphate was at the rate of 12 shillings 4 pence per half-acre plat.

Protein as a factor in the nutrition of animals.—I, A study of the physical constants of fats from swine, A. D. Emmett and F. C. Carroll (Jour. Biol. Chem., 9 (1911), No. 2, pp. XXIII–XXV).—An abstract of a paper read at the 1910 meeting of the American Society of Biological Chemists.

Berkshire pigs, of known ancestry and age, were fed different amounts of blood meal in connection with a basal ration of ground corn and crude calcium phosphate. Lot 1 was fed on a low protein plane, lot 2 on a medium or balanced plane, and lot 3 on a high plane. Chemical constants of the leaf, back, intestinal, and jowl fats were determined.

From this preliminary study of the influence of feed the following conclusions are drawn: “If the ancestry, age, and type of the animals are not considered in comparing the data, the different amounts of protein feed have no apparent influence on the physical constants of the fats. The individual idiosyncrasies of the animals may be as great a factor or greater than that of feed. If litter mates be compared, of which there was one in lot 1 comparable with one in lot 2, and one in lot 2 comparable with one in lot 3, these data show that the differences in the physical constants due to feed were very slight. Here, however, the matter of individuality again may be the controlling factor.

“If the data from the various samples be compared with respect to the kind of fats, they show that the values for the iodin number and melting point are quite different in the case of the back fat when compared with the leaf and composite samples of fat. The averages for the iodin number are 51.23 for the back fat, 45.6 for the leaf fat, and 45.91 for the composite fat. The averages of the melting point determinations for the back, leaf, and composite samples of fat are respectively: 34.1°, 42.8°, and 45.7° C. Comparing all samples of fat in respect to both the protein feed and the kind of fat and without regard to ancestry, age, and type of the animal, or to individuality, the specific gravity, saponification number, the insoluble acids, and the index of refraction appear to be practically constant in each case, averaging for all the samples, 0.9034, 99.64, 95.58, and 1.4395, respectively.”

Pork production with forage crops, F. B. Mumford and C. A. Willson (Missouri Sta. Bul. 95, pp. 561–597).—This bulletin reports the results of 3 years' feeding experiments in studying the adaptability of forage crops for swine, determining the proceeds per acre for pasturing off forage and grain crops, and working out forage crop rotations suitable for hog farms.

The aim was to take a hog weighing about 70 pounds June 1 and by feeding corn produce a gain of 80 pounds by September 1 regardless of the condition of the forage. The hogs, from 8 to 16 per acre, were mostly grades and crosses with Poland China predominating, of early spring farrow, weighing at the beginning of the tests about 50 to 70 pounds each, and in good growing condition. Corn was valued at 60 cents per bushel, oil meal $30 per ton, and gains produced at 6 cents per pound. To determine the amount of pork produced per acre by forage 10 pounds of gain were accredited to each bushel of corn fed and the remaining gains accredited to the forage.

The average amounts of pork accredited to an acre of forage and the net profits were as follows: For blue grass 285.2 pounds, $17.12; alfalfa 596.8 pounds, $35.71; clover 572.2 pounds, $34.11; rape, oats, and clover 394 pounds, $23.64; sorghum 370.5 pounds, $10.15; cowpeas 224.9 pounds, $13.16; and soy
beans 183.1 pounds, $10.99, respectively. The results with soy beans are from the 1910 test only, the 1909 results being discarded on account of poor stand. In hogging off experiments with rye the average amount of pork produced per acre was 244.4 pounds at a net profit of $14.66 per acre, and the corresponding amounts for corn were 395.2 pounds and $23.71.

Among other conclusions drawn are the following: Blue grass made more profitable gains in May and June than later. Red clover ranked among the first as a hog forage because of the palatability of the feed throughout the season, and also because of its adaptability to rotations. Rape fitted well in hog forage crop rotation, if clover was sown with it for the following year. First growth sorghum was adaptable for hogs, and furnished excellent feed through July and August, when other forages were affected by dry weather. Gains made on forage were made at 20 to 30 per cent less cost than gains produced with grain and dry lot feeding. Where forage and grain crops were fed on the land which produced them the minimum amount of fertility was removed, and the physical condition of the soil improved.

[Forage crops for pigs] (Oreg. Agr. Col. Bull., I. ser., 1911, No. 38, pp. 68–70, figs. 2).—In tests made at the Eastern Oregon substation, hogs when feeding on field peas in the field made an average daily gain per head of 1.52 pounds, and produced 256.5 pounds of pork per acre, while the corresponding figures with field peas and hull-less barley were 1.12 pounds per head and day and 190 pounds per acre. The peas were more palatable than the barley, the latter not being eaten until the available peas were gone.

Pig feeding experiments, J. L. Duncan (Dept. Agr. and Tech. Instr. Ireland Jour., 11 (1911), No. 2, pp. 303–310).—This is a continuation of previous work (E. S. R., 21, p. 473).

The gains with 4 lots of 8 pigs each were as follows: On a meal mixture of maize, barley, and pollard, plus potatoes and separated milk the average daily gain was 1.7 pounds, with a total profit on the lot of £6 6s. 3d.; on the meal mixture and separated milk 1.7 pounds, with a profit of £7 13s. 4d.; on the meal mixture and potatoes 1.23 pounds, at a profit of £3 1s. 3d.; and on the meal mixture plus coconut meal, potatoes, and separated milk 1.5 pounds, at a profit of £4 10s. 7d.

On the 5 separate experiments conducted during the last 4 years, wherever there was a slight advantage it was in favor of the lot that was fed the meal and milk only. The coconut meal did not appear to warrant the extra price paid for it.

Pig feeding experiments, B. N. Wale (Jour. Southcast. Agr. Col. Wye, 1909, No. 18, pp. 26, 27).—Foreign barley gave better returns than English barley for pork production, on the average 0.25 pound less of the foreign barley being required for each 1 pound gain in live weight. Coal slack proved a valuable supplement to the grain ration when fed in small amounts.

Feeding experiments with invert potato flakes, Klein (Milchw. Zentrbl., 7 (1911), No. 2, pp. 70–74).—As in a previous experiment (E. S. R., 23, p. 476) there was found to be no advantage in inverting potatoes flakes with diastasolin for feeding to pigs.

A note on the feeding value of coconut and peanut meals for horses, G. M. Rommel and W. F. Hammond (U. S. Dept. Agr., Bur. Anim. Indus. Circ. 168, pp. 2).—In a test with Morgan yearlings and heavy work horses, lasting about 2:1 were substituted for one-half or the entire oat ration, the yearlings showed somewhat larger and cheaper gains on the coconut and peanut meal, those having all their oats replaced giving the best returns. The results were
fairly satisfactory with the work horses, there being a little saving in cost of feed.

"This test seems to indicate that at the prices paid for feed at the time coconut and peanut meal, in the proportion of 2 pounds to 1, can replace oats in the ration of young horses and may be found advantageous for work horses after they have become accustomed to it."

**Sawdust cakes for horses** (Rec. Éaux et Forêts, 19 (1910), No. 19, p. 603; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Instel. and Plant Diseases, 1910, Nov., p. 103).—An account of a stock food which is made by fermenting sawdust, treating it with several chemical processes, and mixing it with rye flour in the proportions of 2 parts of sawdust to 1 part of flour. It is then baked in the same way as bread and used for feeding horses.

**Report of poultryman, J. S. Jeffery** (North Carolina Stu. Rpt. 1909, pp. 23–25).—In the summer of 1908, cottonseed meal was fed for three months to fowls in quantities ranging from 10 to 20 per cent of the total ration. No bad effects were noted. A continuation of the work is now in progress, but among the results already obtained are the following: "Fowls do not relish cottonseed meal as well as meat meal, and therefore do not eat freely of mash containing cottonseed meal. Pullets fed on a cottonseed-meal ration do not develop as rapidly or start to lay as soon as those fed on a ration containing meat meal. Hens have done better than pullets on rations containing cottonseed meal. The addition of bone meal to a meat-meal ration reduced the cost of egg production and increased the size of stock. The addition of bone meal to cottonseed-meal ration did not reduce the cost of production, due probably to the small amount of cottonseed-meal mash eaten."

"The work . . . in testing the value of supplying moisture to the incubator and in disinfecting each incubator just before putting in eggs has been continued. Disinfecting the eggs with a 10 per cent solution of zenoileum has also been tried. This solution was found to be too strong, as it injured the hatching quality of the eggs. The use of a sand tray in the bottom of the incubator to supply moisture has given good results, the percentage of chicks which died in the shell being materially reduced. . . . By the use of hygrometers we found that the use of the sand tray raised the relative humidity an average about 10 per cent above that of similar machines in the same room without the sand tray."

**Production and trade in Peruvian hides** (Bol. Úfic. Assoc. Indus. c Com. Cuio [Turin], 1910, p. 769; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Instel. and Plant Diseases, 1910, Nov., p. 132).—An account is given of this important industry. The goat and kid hides are highly valued for suppleness and strength and the ease with which they can be tanned. The hides from the arid districts of the Sierra are sun dried and exported. Nearly all of the kid skins from Pluera are sent to the United States.

**Nutrition and evolution**, H. REICHNER (London, 1909, pp. XIII+284, fig. 1).—In this book some fundamental laws of nutrition and other biological problems are discussed.

**Nucleus and cytoplasm in heredity**, M. F. GUYER (Amer. Nat., 45 (1911), No. 533, pp. 284–305).—The author points out that in the protein molecule there is an ample basis for the handling of of metabolic energies termed "heredity," as discussed by Reichert and Brown (E. S. R., 22, p. 701).

"The mechanism of heredity would seem to be not so much a local problem of nucleus or cytoplasm as of (1) fundamental species substances, probably mainly protein in nature, together with (2) equally specific enzymic substances which regulate the sequences of the various chemical and physical processes incident to development. As development progresses, more and more kinds of
chemical products are released and in consequence an increasing number of chemical reactions are set going. . . . Looked at this way, the physical basis of heredity could not be considered a series of equipotent units, but rather it must be regarded as being composed of systems of units of different orders of organization and different degrees of coordination."

It is stated that there is no warrant for assuming that chromosomes are more important than other constituents of the nucleus, though they may have many other functions—among them the important one of supplying a particular amount of enzymes—and that the process of mitosis provides for consistency of equilibrium instead of consistency in the number of chromosomes.

On a new method of determining correlation, when one variable is given by alternative and the other by multiple categories, K. Pearson (Biometrika, 7 (1910), No. 3, pp. 248-257).—The object of the present paper is to carry the idea involved in multiple-row correlation tables (E. S. R., 22, p. 671) a stage further by supposing the variable classified into multiple categories to be purely qualitative. The theory of the method is given, accompanied by illustrations to show its adaptability to a wide range of problems.

The determination of sex, J. A. Thomson (Jour. Roy. Micros. Soc. [London], 1911, No. 2, pp. 141-159).—An address by the president of the Royal Microscopical Society, January, 1911, in which recent work on this subject is reviewed. The following conclusion is subjoined: "There may be no sex determinant at all in the usual sense, but what determines sex is a metabolism rhythm, or a relation of nucleoplasms and cytoplasm, or a relation between anabolism and katabolism."

DAIRY FARMING—DAIRYING.

An effect of succulent and nonsucculent fodders upon quality and quantity of milk produced by milch cows, A. Miyawaki (Hoard's Dairyman, 42 (1911), No. 17, pp. 572, 573).—The decline in milk flow was 7.86 per cent when the change of the rations was from corn fodder to corn silage, and 14.19 per cent when the change was made from silage to fodder. The corresponding declines in yield of butter fat were 10.16 and 18.18 per cent.

There was but little change in the percentage of solids-not-fat, the specific gravity, or the acidity when either change was made in the feed, but the slight difference was always in favor of the succulent ration. The sugar content decreased faster when the nonsucculent ration was changed to the succulent ration than when the reverse change was made. Cows receiving a nonsucculent ration consumed 14.01 per cent more total dry matter for a production of a unit amount of milk, 17.77 per cent more for butter fat production, and 17.24 per cent more for solids-not-fat production than when receiving a succulent ration. The cows maintained their weight when on the succulent ration, but lost an average of 0.23 pound per day on the dry ration.

An examination of the figures from 60 farms and 2,638 cows shows that where an average quantity, 20.3 pounds, of hay was used on 22 farms and 519 cows, the daily cost of the cows' ration was 17.4 pence, and the cost of production of a gallon of milk 7.77 pence; whereas on 30 farms (1,324 cows), where the average quantity of hay was 7.8 pounds, these figures were 13 pence and 6.16 pence, respectively, a reduction of 25 per cent and 22.3 per cent, respectively. It is probable that the dairy farmer would get equally satisfactory milk yields at a reduction of cost if less long hay were fed, and if the
bulky fodder consisted of sound straw and chop with a foddering once a day of long hay."

"It would seem undesirable from an economic point of view to feed a greater quantity than 60 to 70 pounds of roots per cow per day."

Influence of temperature on milk yield.—Ventilation of cow byres, C. Douglas (Trans. Highland and Agr. Soc. Scot., 5. ser., 23 (1911), pp. 179-189).—A continuation of earlier work (E. S. R., 21, p. 376). In these experiments 104 pure and crossbred Ayreshires at five different places were used. The percentage of carbonic acid in freely ventilated stables and in those where the ventilation was restricted and the yields of milk are presented in tabular form. The following conclusions are drawn:

"Any restriction of ventilation sufficient to bring the temperature of a byre up to 60° F. leads to a degree of atmospheric impurity inconsistent with the conditions of perfect health. In byres in which the temperatures have been kept down by thorough ventilation in autumn, cows do not suffer either in health or milk yield even from very low temperatures in winter. Whatever waste of food may be entailed in the maintenance of the body heat of cows in colder byres is more than counteracted by the influence of fresher air; while it is evident that the health of animals is much more likely to be promoted by active digestion than by the mere prevention of loss of body heat. It should also be observed that the colder temperature in autumn causes the cows to grow and to retain thick coats of winter hair; so that it is not even certain that the body heat is better conserved in the less ventilated byres than in those which permit the animals to retain their natural coverings. . . ."

A careful attempt should be made to give such a degree and kind of ventilation as will, without creating draughts, keep the temperature of the byre always down to 50°. Special care should be exercised to keep the temperature of the byre well below this point in autumn and early winter.

Variation in the composition of cow's milk with advance of lactation, C. Crowther and A. G. Ruston (Trans. Highland and Agr. Soc. Scot., 5. ser., 23 (1911), pp. 93-102, fig. 1).—The article contains data on the variation in the percentages of fat, ash, protein, and sugar during the lactation period.

"Tests have brought out very clearly the fact that the variations in the composition of milk with advance of lactation may differ greatly in the case of different cows, so that no precise generalizations upon the subject can be formulated. In general the milk is richest in total solids, fat, and albuminoids in the earliest and latest stages of lactation, and poorest about the second or third month. The sugar content tends to decrease steadily with advance of lactation after the first month or so, but the proportion of ash remains approximately constant."

In colostrum the proportion of total solids in milk fell rapidly, the loss being mainly in albumin.

Dairying and milk in Louisiana (Quart. Bul. La. Bd. Health, 2 (1911), No. 2, pp. 36, figs. 12).—This bulletin contains a number of articles on dairy husbandry, the production of sanitary milk in Louisiana, the use of milk as food, and the health train campaign for clean milk, and reports analyses and bacterial counts of milk.

Equipment and sales on a German dairy farm, H. J. Dunlap (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 111, pp. 639-651).—Descriptions of equipment and methods of management of a German farm, including methods of utilizing the crops grown, the character of the cattle kept, the management of milk, the value of the milk, and the price of labor are presented.

Milk tests (Field Expts. Harper-Adams Agr. Col., and Staffordshire and Shropshire, Rpt. 1910, pp. 53, 54).—Milk records of the college herd and analy-
ses of the milk are reported. The average yield of green cheese per gallon of milk for the year was 1.26 lbs., being lowest in June and highest in February.

Milk records. C. Douglas (Trans. Highland and Agr. Soc. Scot., 5. ser., 23 (1911), pp. 222-232).—This is the eighth report of the Scottish Milk Record Committee, in which the records of 9,514 cows are discussed.

Work of the Kiel Experiment Station for dairy products, edited by H. Weigmann (Arch. Vcrs. Stat. Molkere. Kiel, 1909, Nos. 6, pp. 109; 7, pp. 132, pls. 9).—This contains two articles on dairy bacteriology which have been noted from other sources, and also the following articles, which consist mainly of descriptions of the characteristics of new species of bacteria found in milk: Concerning Armenian matzoon, by H. Weigmann; T. Gruber and H. Huss; On the yellow-brown color of hard cheese, produced by Micrococcus chromofusus, by H. Huss; Morphological-physiological studies on two aroma-forming bacteria, Bacillus esterificans and Pseudomonas trifolii, n. sp., by H. Huss; A contribution to the knowledge of bacteria producing the aroma of strawberries; Description of P. fragaroides, n. sp., by H. Huss; On the characteristics of a new species of bacteria isolated from canned milk (Plectridium novum), by H. Huss; and Fat-splitting bacteria (Bacterium lypopoliticum, n. sp.) by H. Huss.

Does colostrum possess bactericidal properties? M. Büb (Besitzt die Kolosstrmilch bakterizide Eigenschaften? Z. Zool. Gesam. Physiol. u. Path. Stoffwechsel, n. ser., 5 (1910), No. 21, p. 526).—The data have been noted from another source (E. S. R. 24, p. 77).

A dairy score card, H. H. Lyon (Hoard's Dairyman, 42 (1911), No. 17, p. 569).—This is a card for scoring dairy barns and milk houses which is used by a large condensed milk firm of New York.

Score card system of dairy inspection, G. M. Whittaker (Hoard's Dairyman, 42 (1911), No. 24, p. 761).—A criticism of the score card, noted above.

The scientific dilution of milk, L. Wainwright (Med. Mag., 20 (1911), No. 3, pp. 158-162).—The difference between cow's and human milk is discussed, and a method is described for modifying cow's milk when used for feeding infants.

Factors affecting the per cent of fat in cream from farm separators, C. H. Eckles and H. S. Wayman (Missouri Sta. Bul. 94, pp. 517-558, figs. 12).—This bulletin reports a series of experiments which were conducted to ascertain the causes of wide variations in the percentage of fat in cream from hand separators. The conditions covered by the investigations were those which were thought certain to vary on every farm, namely, (1) speed of separator, (2) temperature of milk separated, (3) rate of inflow to separator bowl, (4) richness of milk separated, and (5) acidity. It was assumed that the percentage of fat in cream is influenced by the amount of water or skim milk used to flush out the bowl at the end of the run and by the adjustment of the cream screw. Five different makes of hand power, centrifugal cream separators were used.

In a preliminary test with water 80 per cent more water was delivered from the skim milk tube when the separator was being fed its full capacity than under the ordinary rate of inflow, showing that the skim milk tube does not commonly run to its full capacity.

The usual explanation that by turning the cream screw nearer the center richer cream is obtained because the richer cream found near the center is held not to be the full explanation. It is pointed out that turning the cream screw nearer the center causes an increased outflow from the skim milk tube and a relatively smaller amount of and richer cream.

In testing the effect of speed of separators each machine was tested at the speed recommended by the manufacturers, and at three-fourths and one-half this speed. It was found that with one exception, set for thin cream, the
greater the speed of the machine the higher the percentage of fat in the cream, and this effect was much more marked when the cream screw was set for thick cream. Within ordinary limits the greater the speed the less the amount of fat remaining in the skim milk. This did not vary to any marked extent whether the separator was set for thin or thick cream. The rate of inflow was uniformly increased by the speed. The explanation given for this is not that the greater the speed of the separator the more milk will run through it in a given time, but that it is due to suction caused by the flow of air through the machine. The capacity of the separators did not vary to any extent whether set for thick or thin cream.

In ascertaining the effect of the temperature of the milk tests were made at 70°, 80°, and 90° F., respectively. Contrary to the general assumption, the results indicate that the higher the temperature of the milk separated the thinner the cream. This was found to be more marked when the separator was set for thick cream than for thin cream. The results show that the colder the milk separated the greater was the percentage of fat in the skim milk. The capacity of the machines did not vary materially with milk of high or low temperature.

In testing for the effect of the richness of the milk separated, one lot was separated under normal conditions, and the skim milk obtained was used in reducing the second lot to about 3 per cent fat. The only marked variation was the percentage of fat in the cream, which was found to vary practically in direct proportion to the percentage of fat in the milk separated. Within ordinary limits the richness of the milk had no appreciable effect upon the loss of fat in the skim milk or upon the capacity of the machine.

In the experiments on the effect of the rate of inflow, three runs were made with each lot of milk: First, with the feed can full of milk; second, half full; and third, with the milk 1 inch from the bottom. The rate of inflow was changed in other trials by the faucet. In general a decrease in the inflow resulted in (1) less cream in proportion to skim milk, (2) higher percentage of fat in the cream, (3) no appreciable effect as to the loss of fat in the skim milk.

Acidity had but little effect except that with sour milk there was a tendency for the percentage of fat in the cream to be increased, especially when the cream screw was set for thick cream.

The effect of dirt in the tubes and of clogging of the bowl is also discussed.

MilK powdered starters in creameries. C. Larsen and W. White (South Dakota Sta. Bul. 123, pp. 3-11).—In a preliminary investigation on the use of milk powder solutions in the place of natural milk for starter making it was found that the best degree of concentration to supply conditions for bacterial growth was in the proportion of 3 ounces of powder to 1 quart of water. The comparative development of acidity and bacteria in mother starters, prepared from both milk powder and natural skim milk, is presented in tabular form. The growth of both bacteria and the development of acid and flavor was normal. Stained preparations of the bacteria from milk powder solutions appeared the same under the microscope as those grown in natural milk.

A comparison of the specific gravities, amount of acid developed, and number of bacteria per cubic centimeter showed that the solution of 3 ounces of powder in 1 quart of water furnishes the bacteria conditions resembling very closely those formed in natural milk. Butter made from the milk powder starters scored equally as high as when made of natural milk starters, both when fresh and when 2, 4, and 6 weeks old. The scorched flavor in the milk powder was not detected in any of the samples of butter made. The cost of the powder starters is somewhat higher than that from those made of milk, it being estimated at 0.3 to 1 cent per pound of butter made, yet they are recommended for
large central plants in cities where an ample supply of good milk can not be obtained at the usual price.

The method of making the milk powder starters is described.

Propagation of starter for butter making and cheese making. E. S. Guthrie (New York Cornell Sta. Circ. 10, pp. 13-16).—This contains directions for propagating starters for butter and cheese making.

On the composition of uninspected Holland butter in the Province of North Brabant in the years 1905-1910, H. Sprinkmeyer (Ztschr. Untersuch. Nahr. u. Genussmittel, 21 (1911), No. 7, pp. 411-416).—Results of the Reichert-Meissl test are presented in tabular form and show that since the butter has been inspected the adulteration with foreign fats has been greatly reduced.

Development of cooperative dairying in Russia, A. A. Kalantar (Uzheg. Dept. Zeml. [Russia], 30 (1909), pp. 555-573).—The first cooperative dairying in Russia was in making cheese in the late sixties. Though many persistent attempts were made by the peasants to follow the methods of the Swiss cheese makers, they ended in failure because of the long time required for ripening and the slow monetary returns. The first cooperative creameries were started in the Tobolsk Government in 1896 and have been so successful that in 1900 there were in Siberia 1,400 cooperative butter-making factories, most of which were in the Tobolsk and Tomsk Governments. Cooperative butter making has been less successful in European Russia because of the poverty of the peasants who need a quick return in cash for their products, but outside aid has been recently brought to their assistance and the number of cooperative factories has been increasing.

**VETERINARY MEDICINE.**

The construction, equipment, and management of veterinary quarantine and epizootic stables for cavalry troops, with investigations in regard to damp foundations, their detection, and remedy, F. Ehrle (Über Bau, Einrichtung und Betrieb von Veterinärlazaretten, Seuchen- und Quarantäneställen bei den berittenen Truppen mit Untersuchungen über die Mauerfeuchtigkeit, ihre Feststellung und Abhilfe. Inaug. Diss., Univ. Bern, 1910, pp. 16, tables 2).—This work deals chiefly with military stable hygiene, and has particular reference to the construction of stalls for quarantining against such diseases as erysipelas and pneumonia. It lays special stress upon the methods for detecting damp foundations and the removal of the cause thereof.

In regard to increasing the disinfecting value of phenols by the addition of acids, E. Hailer (Arb. K. Gesundh.-amt., 33 (1910), No. 3, pp. 500-515).—The disinfecting value of phenols and the three cresols can be increased by the addition of such acids as oxalic, sulphuric, acetic, citric, tartaric, and boracic, and as regards potency in the order stated. Where no phenols were employed, sulphuric acid was found to be a better disinfectant than oxalic, while tartaric, citric, and acetic acids were about equally effective.

The toxicity of amyl acetate, W. Salant (Proc. Soc. Expd. Biol. and Med., 7 (1916), No. 5, pp. 154, 155).—In the pharmacological laboratory of the Bureau of Chemistry of this Department it was determined that *from* 4 to 6 ec. per kilogram of amyl acetate injected into frogs caused paralysis and coma in from 15 to 30 minutes. These symptoms lasted 24 hours, with final recovery. In some cases such doses proved fatal. Larger doses were invariably fatal. Experiments with 2.5 ec. per kilogram administered in 2 per cent suspension in water, failed to cause any symptoms.
"Experiments were also made on rabbits. Amyl acetate was given by mouth in aqueous suspension or dissolved in neutral olive oil. Five cc. of amy acetate given by mouth to rabbits weighing about 1,500 gm. did not produce any symptoms in any of the animals experimented upon, except one in which the dose proved fatal within 24 hours after its administration.

"The effect of amy acetate on blood pressure was studied in dogs. One cc. injected directly into the circulation within 25 seconds caused a fall of blood pressure amounting to 56 per cent. When the vagi were eliminated the fall of blood pressure was still greater. In both instances there was a marked slowing of the pulse."

Notes on Crotalaria burkeana and other leguminous plants causing disease in stock. J. Burt-Davy (So. African Jour. Sci., 7 (1911), No. 6, pp. 269-277).—In addition to an account of C. burkeana, a native plant of the Transvaal and the disease which it causes, known to farmers as "styzizékté," brief mention is made of several other plants causing neuritic troubles.

Report on the operations of the veterinary sanitary service of Paris and the Department of the Seine for the year 1909, H. Martel (Rap. Opér. Serv. Vét. Sanit. Paris et Dépt. Seine, 1909, pp. 330, fgs. 17).—Part 1 of this volume reports on the occurrence of contagious diseases (pp. 1-77); part 2 on meat inspection (pp. 78-236); part 3 on the inspection of milk (pp. 237-250); part 4 on the inspection of several classes of establishments, including abattoirs, etc. (pp. 251-254); and part 5 on work of the laboratories (pp. 255-322). Statistical data, etc., are given on rabies, tuberculosis, glands and farcy, hog cholera, and charbon.

Tropical diseases of animals (Trans. Int. Internat. Vet. Cong. The Hague, 4 (1909), pp. 212-244).—This report includes papers by Dschunkowsky on the protozoan diseases of animals in Transcaucasia; by S. Luks on the piroplasmosis of the hedgehog, due to *Piroplasma erinacei*, that occurs in the vicinity of the Surnabad rinderpest-serum station, and brief mention of piroplasmosis in the fox due to *P. vulpis*; and by Tartakowsky on the etiology and pathology of spirochetosis of geese and on piroplasmosis of the bat *Vespertilio noctula* and the agent that transmits it (thought to be *Argas vespertilionis*). See also a previous note (E. S. R., 22, p. 386).

The relation between hypersensitiveness and immunity, E. Friedberger (Berlin. Klin. Wehnschr., 47 (1910), No. 32, pp. 1496-1492; Deutsch. Med. Wehnschr., 37 (1911), No. 11, pp. 481-487, dmgs. 5; abs. in Ztschr. Immunitätsf. u. Expt. Ther., 11, Ref., 3 (1910), No. 11, pp. 979, 986).—According to this work, immunity and anaphylaxis are not antagonistic to one another, the only difference being in the end effects. This is due to the different properties of the antigens in question and the different quantitative relations.

The problem of protein anaphylaxis, H. Pfeiffer (Das Problem der Einwirkung proteins anaphylacticum. Jena, 1910, pp. 231, dmgs. 7).—This work, which has particular reference to the problems of anaphylaxis for forensic purposes, contains the following chapters: Historical review; sensitization and the preanaphylactic phenomena; reinjection; active anaphylaxis; antianaphylaxis; passive anaphylaxis and the method for measuring the anaphylactic immune bodies; test tube experiments: the significance of anaphylaxis for the practical differentiation of proteins; and some practical examples in anaphylaxis. A bibliography is appended.

Egg white was introduced into animals and the blood and tissue extracts from them tested for its presence by sensitizing guinea pigs.

The work shows that egg white injected into the stomach, rectum, or peritoneal cavity of a rabbit may be, in part at least, absorbed unchanged. Egg white injected intravenously in rabbits quickly disappears from the circulating blood, but may subsequently be detected in the peritoneal cavity, and by the sensitization test in certain organs. It may also be detected in the bile. When carried into the tissue after intravenous injection it may be washed back into the blood current by transfusion with salt solution. The injection of egg white intravenously in rabbits decreases after a few hours the total protein in the blood, but injection in large amount proves fatal.

Biological differentiation of the protein of mice and various species of rats, F. Graetz (Ztschr. Immunitätsf. u. Exp. Ther., I, Orig., 6 (1910), No. 4, pp. 527-543; abs. in Zeitschr. Gesam. Physiol. u. Path. Stoffwechsels, u. ser., 6 (1911), No. 1, p. 18).—It is not possible, according to the author, to differentiate the proteins of the various species of rats (Mus domesticus, M. rattus, and white rats) with the precipitin and complement-binding or fixation and anaphylaxis reactions. On the other hand, however, it is possible with the complement-binding and precipitation methods to differentiate the protein from the various species of rat from that of the white mouse.

Anaphylaxis with plant substances, T. Azuma (Beiträge zur pflanzlichen Anaphylaxie. Diss., Osaka, 1910; abs. in Ztschr. Immunitätsf. u. Exp. Ther., II, Ref., 3 (1910), No. 11, p. 996).—Anaphylaxis is not so easily produced with plant antigens as with animal antigens. The experiments, which were conducted with soy beans, horse beans (Vicia faba), rice, and barley, show that anaphylaxis can be produced by giving either one large initial dose of the antigen or repeated small doses.

Precipitating characteristics of plant antigens, T. Azuma (Beiträge zum Studium der präzipitierenden Eigenschaften pflanzlicher Antigene. Diss., Osaka, 1910; abs. in Ztschr. Immunitätsf. u. Exp. Ther., II, Ref., 3 (1910), No. 11, p. 994).—Seed and seed-germ extracts from rice, barley, horse beans (Vicia faba), and soy beans are capable of producing precipitins. The normal sera of various animal species were found to give a precipitation with these plant extracts. The precipitin-forming substance of the plant extracts is destroyed by autolysis. The precipitogenes are weakened by a temperature of 60° C., and absolutely checked at 80°, but at 100° they are revived.

The action of some lipoid substances upon ultrafilterable viruses, Y. FukuHara (Ztschr. Immunitätsf. u. Exp. Ther., I, Orig., 9 (1911), No. 1, pp. 75-86).—Oleic acid was found to exert a strong destructive action upon all viruses, including chicken pest vaccine virus and the virus of rabies. Sodium and potassium oleate and lecithin, however, did not possess such a capacity, save for the virus of rabies. The bactericidal action of pyocynase, according to the author, is probably due to the presence of an alcohol-soluble lipoid substance which, when isolated, is more powerful than the original pyocynase. Coll lipoids did not have any effect upon the various viruses.

Methemolytic reactions, O. Bail and S. Suzuki (Ztschr. Immunitätsf. u. Exp. Ther., I, Orig., 9 (1911), No. 1, pp. 42-60).—A specific prepared solution of sensitized blood corpuscles is still capable of fixing large amounts of hemolytic immune bodies in the same manner as intact sensitized blood corpuscles. From this it appears that the hemolysis which goes on between the blood corpuscles and the serum does not go on to the final reaction, but simply acts as a preparer or an accompanist for the reacting substances contained in the blood corpuscles. This is termed by the author, “methemolysis.” The excessive fixation of immune bodies by the blood corpuscles, which are not necessary for
the hemolysis, can be explained by methemolysis, which follows the usual hemolysis.

In regard to the method of combination of the hemolytic amboceptors, K. Kawashima (Biochem., Ztschr., 31 (1911), No. 1–2, pp. 135–141). — The results show that the amboceptors from the dog and rabbit behave practically alike in their manner of combining with goat's blood.

A simple method for counting the eosinophils, R. Dunger (München. Med. Wchnschr., 57 (1910), No. 37, pp. 1942–1944; abs. in Zentralbl. Gesam. Physiol. u. Path. Stoffwechsels, u. ser., 5 (1910), No. 22, p. 853). — The counting fluid utilized for this consists of 10 cc. of a 0.1 per cent aqueous solution of eosin, 10 cc. of acetone, and 80 cc. of water. The blood is diluted with this fluid in the proportion of 1:10, shaken for from three to five minutes, and a portion of it brought into the counting chamber.

Staining the anthrax bacillus, Forth (Berlin Tierärztl. Wchnschr., 27 (1911), No. 8, pp. 129–132). — This is a simplified, accurate, and rapid method, and which utilizes azur II and Nocht's red from methylein blue as the dyestuffs.

The cultivation of the spongiform anthrax bacillus with amino acids, J. Bieliecki (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 3, pp. 100–102). — A feeble development of this bacillus was noted in solutions of asparagin, glycine, glutaminic acid, and leucin. The best results were obtained with asparagin.

Two cases of brain anthrax, A. Weffer (Ztschr. path. ab. u. prakt. Tierheilk., 32 (1909), No. 48, pp. 532, 583; abs. in Berlin Tierärztl. Wchnschr., 27 (1911), No. 8, p. 134). — Among 1,500 head of cattle in one community, 75 per cent of them became slightly affected with this disease. The fatalities at this period were limited to 4 sucking calves. After three to four weeks the author noted that the hair in about 10 per cent of the infected animals became long, straight, and uneven, and that despite the hot weather the animals did not sweat. Clinically, the condition was characterized by a body temperature of about 40° C., a superficial respiration of 60 per minute, loss of appetite, diminution in lactation, and salivation. A few of these animals succumbed with cachexia.

The chemotactic action of glands bacillus extracts, Hoestetter (Arch. Wiss. u. Prakt. Tierheilk., 36 (1910), Supp., pp. 153–160; abs. in Berlin Tierärztl. Wchnschr., 36 (1911), No. 8, pp. 247, 248). — The toxins were found to act only upon the polymorphonuclear neutrophilic leucocytes.

Hepatic distomiasis (sheep rot) in man, G. R. Ward (Brit. Med. Jour., 1911, No. 2625, pp. 933–934, figs. 2). — The author finds records of 24 cases of the occurrence of liver fluke (Fasciola [Distoma] hepatica) in man, 13 or 14 of
which appear to be authentic. The biology of the parasite is discussed, together with an account of the course of the disease as it occurs in man.

On some examinations of blood of the horse, ox, and sheep in Madagascar, J. Mamet and Lloiselt (Rev. Gén. Méd. Vét., 17 (1911), No. 198, pp. 339-335).—The authors state that in Madagascar piroplasmosis occurs in the horse, ox, and sheep. The bovine form, which is known to the natives as "beravy" or "tazan'onym," is not considered to be of economic importance, as it always occurs in a benign form. Nevertheless the authors think that its diminution of the resistance of cattle to other diseases may explain the great annual loss caused in Madagascar and Bara by tuberculosis and charbon, particularly the acute course run (6 to 12 hours) by charbon in cattle. Equine piroplasmosis is more grave than bovine and may prove fatal. This disease in sheep explains the difficulty encountered in raising them in Madagascar.

The species of tick or ticks that serve as active agents in the transmission of these affections remain to be determined.

On the development of Piroplasma parvum in the organs of cattle suffering from East Coast fever, R. Gonder (Berlin. Tierzrztl. Wehnschr., 26 (1910), No. 27, 537-539, figs. 17).—This account of Theliera (Piroplasma) parva has been previously noted from another source (E. S. R., 24, p. 83).

The development of Theliera parva, the cause of East Coast fever of cattle in Africa, R. Gonder (Arch. Protistenk., 21 (1910), No. 2, pp. 143-164, pls. 5, fig. 1).—This is a detailed report of the investigations noted above, with references to the literature, of which a bibliography of 26 titles is appended.

The prevention and eradication of East Coast fever, A. Theiler and J. M. Christie (Transvaal Dept. Agr. Farmers' Bul. 129, 1910, pp. 15, figs. 7; Transvaal Agr. Jour., 9 (1910), No. 38, pp. 1-3, figs. 7).—A general consideration of the disease, the ticks which transmit it, and preventive and remedial measures.

Trypanosome diseases of domestic animals in Uganda, IV, V, D. Bruce et al. (Proc. Roy. Soc. [London], Ser. B, 33 (1911), No. B 563, pp. 176-186, pls. 3, figs. 2).—Continuing previous work (E. S. R., 24, p. 586), the authors find that Trypanosoma uniforme resembles T. vivax in shape and general appearance but differs markedly in size and that it also resembles T. vivax in not being pathogenic in the smaller laboratory animals. There is no evidence available as to what is the carrier of T. uniforme.

"T. nanum" is indistinguishable from T. pectorum either in the living condition or when fixed and stained. It differs from T. pectorum in not being pathogenic to the smaller laboratory animals. The carrier of T. nanum is probably the same as that of T. pectorum, as both diseases occur under the same conditions, but there is no evidence available as to what the carrier is.

Experiments to ascertain if antelope may act as a reservoir of the virus of sleeping sickness (Trypanosoma gambiense), D. Bruce et al. (Proc. Roy. Soc. [London], Ser. B, 33 (1911), No. B 564, pp. 311-327).—While antelope have not been found naturally infected with T. gambiense, the authors have discovered that water buck, bush buck, and reed buck can readily be infected with a human strain of this trypanosome through the bites of infected Glossina palpalis.

"Antelope of the water buck, bush buck, and reed buck species, when infected with the virus of sleeping sickness, can transmit the infection to clean laboratory-bred G. palpalis. This transmission of the infection to clean laboratory-bred flies may occur at least 81 days after the last feed of the infected flies on a buck. G. palpalis, when infected with the virus of sleeping sickness obtained from the blood of infected antelope, are capable of transmitting the virus to susceptible animals."
Experiments to ascertain if the domestic fowl of Uganda may act as a reservoir of the virus of sleeping sickness (Trypanosoma gambiense), D. Bruce et al. (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. 564, pp. 328, 329).—The experiments here reported show that the Uganda fowl can not act as a reservoir for the virus of sleeping sickness.

Notes on a human trypanosome transferable to animals in northern Rhodesia, L. E. W. Bevan (Vet. Jour., 67 (1911), No. 427, pp. 41-47).—A trypanosome which has been definitely identified as Trypanosoma vivax was isolated from a European arriving in southern Rhodesia from the northern part of the colony. Laboratory animals, a sheep, and a mule were readily infected through inoculation of the virus.

Auto-agglutination of red blood cells in trypanosomiasis, W. Yorke (Ann. Trop. Med. and Par., 4 (1911), No. 4, pp. 529-552).—Auto- and iso-agglutinin are present in the blood of cases of sleeping sickness and of animals infected with trypanosomiasis. Reaction between auto-agglutinin and red blood cells takes place only at low temperatures. Auto-agglutinin can be removed from plasma by absorption with the erythrocytes of the same animal at 0° C. The reaction between auto-agglutinin and red blood cells is reversible. Auto-agglutinin exists in small amounts in the blood of many normal animals. Auto, iso, and hetero agglutinin are frequently present in much greater amount in the blood of infected animals than in that of normal animals, and it is due to this fact that clumping of the red blood cells is often visible in fresh cover-slip preparations of the blood of infected animals. From the red blood cells of an infected animal which have been agglutinated in the cold by the plasma of the same animal an active substance can be extracted with normal saline solution at 37°. This substance agglutinates not only the red cells of the same animal and other members of the same species but also those of many animals of different species.

"It is to be inferred from the information at present available that a marked degree of auto-agglutination of the red blood cells is an extremely rare occurrence apart from an infection with trypanosomes."

The reaction curve of the human and the bovine type of the tubercle bacillus in glycerin bouillon, T. Smith (Jour. Med. Research, 23 (1910), No. 2, pp. 185-204, 211).—The basic principles involved in this work have been previously noted (E. S. R., 17, p. 294), but in this article the author has gone over his methods again and determined more precisely the conditions which will make uniform results possible. In addition to this, he reviews the results obtained by others with the method. He also tested the correctness of Duval's theory that the acid production by the tubercle bacillus is due to autolytic processes following the death of the bacilli which act upon the glycerin molecule.

The results of these tests indicated that "wherever growth was definitely checked by chloroform or heat and the culture remained free from outside contamination the change in reaction was usually in the direction of a higher acidity. This change was slight, from 6 to 0.8 per cent ad maximum. At the termination of the test, usually from two to three months after the treatment of the culture by heat or otherwise, the bacillar mass was collected and subjected to centrifugal action to determine the amount. The control cultures which were left to finish their growth contained as a rule twice as much bacillar deposit as those heated or chloroformed or exposed to water, salt solution, etc. The amount of acid production in them was, however, five to seven times as great as that which took place after the cultures had been checked."

The author, however, is not inclined to adopt the Duval hypothesis, and still coincides with Siebert in his belief that the second part of the reaction curve is largely associated with the life processes, and that very little is due to the
process of disintegration. He believes that were the acid wholly of post-mortem origin its neutralization could hardly be expected to revive a portion of the bacilli to renewed activity.

Some further tests which were made with media containing various amounts of glycerin showed that two processes may occur, one being a rapid fermentation and the other a later disintegration process. The author was able to confirm a previous conclusion that where only small amounts of glycerin (1 per cent in bouillon) are present the tubercle bacillus produces an alkaLin reaction. When a slight acid reaction in 1 per cent glycerin bouillon is present, this is due to a disintegration process. “The difference in the reaction of 1 and 4 per cent glycerin bouillon in the human type after three months is probably due to acid production in glycerin not used up in the growth of bacilli. Under the conditions and with the amount of peptone, etc., supplied it is evident from the results that from 1.5 to 2 per cent glycerin represents the average amount utilizable. With increased amounts of peptone, etc., and the neutralization of the acids formed, more glycerin may perhaps be consumed.”

In order to determine the correctness of Griffith’s statement that the degree of acidity produced is a function of the amount of growth rather than being specific of a type, the author performed some tests, the results of which show that where acids are produced the bulk of growth does not seem to increase beyond a certain limit, this being dependent upon the amount of glycerin present, and probably because the acids inhibit. The diagrams also “prove that 2 per cent glycerin in bouillon is not sufficient to bring out the differences between the bovine and the human type in all strains.”

An experiment to determine the behavior of the bovine and human type of bacilli in the presence of dextrose showed that in a flask containing acid bouillon without either dextrose or glycerin only a slight multiplication of the bacilli took place. Flasks containing dextrose remained practically neutral. The author does not believe dextrose a good substitute for glycerin. All claims of transformation by passages of the human into the bovine type or vice versa must, according to him, pass the test of the reaction curve as well as the others before such transformations can be accepted as accomplished facts.

The relative importance of the bovine and human types of tubercle bacilli in the different forms of human tuberculosis, W. H. Park and C. Krumwiede, Jr. (Jour. Med. Research, 23 (1910), No. 2, pp. 265-368; Centbl. Bakt. [etc.], 1. Abl., Ref., 47 (1910), No. 22-24, pp. 673-680).—These investigations were conducted for the purpose of determining the relative importance of human and bovine types of bacilli in the prevalence of tuberculosis in man. The cases selected were taken without regard to the age of the patient or the type of the disease. The bacterial cultures employed were in every instance isolated through the guinea pig and egg media were used to cultivate the various strains obtained.

When using Lubenau’s medium (glycerinated egg) the bovine type of bacillus could only be sparsely propagated or not at all, while the human type flourished. The authors believe this to be a good differential method.

To control the difference between the plain egg and the glycerinated egg media the investigators made use of a glycerin-potato medium free from coagulable protein. It was noted that when adding glycerin bouillon to the egg media for growing the bacilli from the egg to the bouillon, the virus of the bovine type failed to form a pellicle in the first few generations, whereas on the other hand, the human type formed a pellicle at the outset without any trouble. Slightly perceptible differences alone could be noted in the morphology of the bacilli, and only when they were cultivated through some generations.
As regards virulence, the bovine type was found to cause generalized tuberculosis in rabbits in doses of 0.01 mg. when given intravenously. Human virus when employed in the same dose never produced a generalized tuberculosis, and in many instances it produced nothing at all. Although there is a slight tendency to generalization in doses of 1 mg. of human virus, the average findings showed that the dose may be localized in the same organ as with the 0.01 mg. dose.

Where the virulence for calves was tested the injection was made subcutaneously and in 50 mg. doses. The human type of bacillus caused only local lesions, while the bovine bacillus caused a progressive form of the disease. The authors believe the time for the necessity of using calves for routine differentiation has passed.

According to the authors, all bacilli in cattle and man fall into two types, the bovine and the human, and the various types can be distinguished culturally with surety. Numerous strains of bacilli which were reisolated from calves did not show any change from their previous characteristics. It appeared that the resistance in calves was from 140 to 142 days. Forty-four of the strains were tested with the Smith reaction, and 2 viruses which were isolated from man (human type) gave typical bovine curves.

The results of numerous examinations of the bacilli from 297 patients above 16 years of age showed that only in one instance was a bacillus found of bovine origin. Among 54 cases where the ages ranged from 15 to 16, 9 were infected with the bovine type, and in 22 out of 84 children under 5 years of age the bovine type was also found. In order to correlate and compare their findings with other investigators, 1,040 cases were taken from the literature, and from this it was noted that out of 686 tuberculosis subjects 16 years of age or over, 9 had the bovine type of bacillus, while in 126 cases between the ages of 5 and 16 years, 13 were infected with the bovine type, and out of 120 tuberculous subjects under 5 years of age, 59 had the bovine type of bacillus. The greater portion of the infection by the bovine type of bacillus manifested itself by attacking the cervical glands and also within the abdominal cavity. The bovine type evidently plays an important and very significant part in the tuberculosis of the child, and thus prophylaxis must be extended to its exclusion.

Studies in regard to antigen formation on protein-free nutrient media.—

I. Tuberculin, E. Löwenstein and E. P. Pick (Biochem. Ztschr., 31 (1911), No. 1-2, pp. 142-152).—The results show that it is possible to obtain an active tuberculin from a protein-free medium and as a true metabolic product of the tubercle bacillus. It is a heat-stable, dializable, and alcohol-insoluble substance which does not yield the biuret reaction, but is precipitable in an acid solution with tannic acid, potassium mercuric iodid, and mercuric sulphate, and is decomposed by a pepsin-hydrochloric acid solution, and by a trypsin-sodium bicarbonate solution.

Immunization of cattle against tuberculosis, F. C. Schroeder and J. R. Mohler (Amer. Vet. Rec., 38 (1910), No. 2, pp. 161-183).—After reviewing the literature on the subject and the present status in regard to the efficiency of the various measures for immunizing cattle, the authors give a preliminary report of their work on calves with von Behring's, Pearson's, and Heymann's methods. In addition, some tests are reported in which an attempt was made to confer immunity by subcutaneously injecting tubercle bacilli of various degrees of virulence and by transfusion of blood from artificially immunized animals to susceptible animals.

From the work it is seen "that 3 of the 9 cattle treated according to the method of von Behring and afterwards exposed contracted tuberculosis, that one of the 9 cattle treated by the method of Pearson and afterwards exposed
contracted tuberculosis, and that of 14 checks or untreated control animals 12 became infected on exposure. Of the 8 animals that received injections of bovine tubercle culture subcutaneously into the ends of their tails (4 old and 4 young animals) all but one young animal contracted disease as the result of the injections. The one that escaped disease from the injection also resisted tuberculosis on exposure. Of the 5 cattle that received human culture injections into the ends of their tails 2 became immune without inoculation disease, 2 were immune but had slight inoculation disease, and 1 had both inoculation and exposure disease. The injection of tubercle cultures under the skin of the neck of animals caused them all to contract tuberculosis.

"Careful autopsies of the cattle treated by intravenous inoculations of tubercle bacilli, according to the methods of von Behring and Pearson, show that the more or less attenuated tubercle bacilli that engender immunity against tuberculosis rarely leave the treated subjects wholly free from lesions that can be accounted for in any other way than as due to the pathogenic activity within the animal's body of the injected bacilli. . . ."

In addition to the above, "12 cattle and 10 hogs were inoculated with Heymann's capsules. The animals were divided into three groups, and one group of hogs and cattle was exposed immediately after treatment to a tuberculous environment, a second about two months later, and a third about two months after the second. With each group of hogs a similar number of untreated hogs were exposed as checks. . . . Among the Heymann's treated hogs one contracted generalized tuberculosis from the treatment and one died prematurely as the result of an injury. When the remaining 8 hogs with their 10 checks were killed, after an exposure to natural infection varying from 8 months to a year, all the principals and checks were found to be affected with tuberculosis. Not one of either lot had escaped the disease, and the lesions in the treated animals were in no respect different from those found in the checks. Hence, it is very clear that Heymann's method is absolutely worthless for hogs."

In regard to the transfusion tests it could be noted "that the experiments gave wholly negative results, and hold out no encouragement as being a means by which tuberculosis can be treated or the resistance to infection strengthened."

The authors finally conclude that "no system of bovo-vaccination has reached a stage at the present time that justifies its use in common practice."

Onchocerciasis in cattle, with special reference to the structure and bionomic characters of the parasite, R. T. Leiper (Rpts. Local Govt. Bd. [G. Brit.], Pub. Health and Med. Subjs., n. ser., 1911, No. 45, pp. 6-16, pls. 3; Jour. Trop. Med. and Hyg. [London], 14 (1911), No. 6, pp. 87-93, figs. 13).—"The parasitic nodules in Australian beef are, without exception, due to the presence of long thread-like worms of the genus Onchocerca. The diseased condition, onchocerciasis, is not peculiar to Australian cattle, but occurs also in other animals and in various parts of the world, including the United States of America. The parasites belong to a group of worms that require to be taken up by a biting insect, and to undergo a certain degree of development therein before they can be transmitted to another warm-blooded animal. The worms and their young do not appear to be capable of surviving for more than a few hours the death of the cattle. No evidence of the vitality of the worm or its embryo has been met with in the case of Australian beef reaching this country." The direct development of the parasite in man as a result of eating infected meat is impossible. The nodules are the product of changes taking place in the tissues as a result of some acrid toxin excreted by the worms. In the author's opinion their presence in meat intended for human consumption is undesirable for this reason.

A bibliography of 15 titles is appended.
The forensic detection of newly lactating cows, J. Bauer and M. Sassenhagen (Berlin, Tierärztl. Wochenschr., 27 (1911), No. 8, pp. 141–144, figs. 2).—As it often becomes a legal question as to whether a certain cow is in the first stages of lactation, the authors discuss the various criterions, such as the presence of a calf, its age, witnesses of the birth, the puerperal changes in the genitals and udder, the condition of the mammary gland and its secretion, and the value of the complement-binding or fixation method for testing the secretion. The method for making the hemolytic test is described in detail.

Treatment of prolapsus uteri, R. Grődák (Allatorvosi Lapok, 33 (1910), No. 15, pp. 171, 172; abs. in Berlin, Tierärztl. Wochenschr., 27 (1911), No. 8, p. 134).—The author replaced a prolapsed uterine in a cow in a lying-down position, using no antiseptics except a little lukewarm water.

The occurrence and significance of streptococci in milk, J. Baehr (Vorkommen und Bedeutung der Streptokokken in der Milch. Inaug. Diss., Univ. Bern, 1910, pp. 74, pl. 1).—Only 2 out of 81 samples of milk collected in Düsseldorf and thereabouts were found to contain the Streptococcus pyogenes. In one of the two cases their presence was due to udder disease. In almost all of the milks (75 per cent) streptococci could be detected with Petruschyk's method. They were identical with the Streptococcus lacticus described by Kruse, and probably originated from the feces.

Investigations in regard to white scours in calves, C. Titze and A. Weichel (Arb. K., Gesundsamt., 33 (1910), No. 3, pp. 516–558).—Following a detailed review of work already reported in regard to this disease, the authors give the results of their biological and enzootiological investigations, which were begun in June, 1908.

In the biological work 210 calves' dysentery strains from various sources were examined and compared with various strains of human dysentery and other intestinal bacteria. Out of the 210 strains, 160 were found to be Bacterium coli commun, 24 B. enteritidis (Gärtnert), 16 pseudocoli bacilli, 4 paracoli bacilli, and 2 strains each of Bacillus paratyphosis B, B. lactis aerogenes, and B. proteus mirabilis. A bacillus was also isolated which stands intermediate between the Gärtnert bacillus and the paratyphoid B bacillus, and which was differentiated from the former only by the agglutination test, as in other respects it was the same. The authors propose the name of Bacillus paracoli for it.

It was furthermore noted that the clinical manifestations of white scours could be produced with the dysentery coli bacilli, pseudocoli bacillus, Gärtners' bacillus, and paracoli bacillus, and in rare instances with the paratyphoid B bacillus. The Gärtnert bacilli and the paracoli bacilli were found to produce the severest forms of the disease in suckling calves. On autopsy in many instances the paracoli and paratyphoid B bacilli were found in the muscles and organs of the same calf, and from this the authors conclude that the disease is probably not a specific one. The bacilli were excreted in the urine and feces from the infected animals.

The authors further found that in most instances the infection was extra-uterine, and in the majority of cases the infective agent was taken up with the food. The strains of the dysentery bacterium causing the disease in man could not be noted in the enzootics investigated, nor were the authors able to note any relation of the Bacillus pyocyaneus, B. proteus, and the various species of coci to the disease in calves. The question of the dissemination and combating of the disease is also discussed.

the name of "garrotilho" a sporadic disease of hogs occurs in Brazil which is characterized by a progressive enlargement of the cervical glands and an edematous infiltration in the locality of the pharynx and trachea. Symptomatically it shows dyspnea associated with an audible bruit and difficulty in swallowing. Death generally occurs suddenly and a few days after the onset of the disease as a result of asphyxiation. Anthrax bacilli were isolated from the glands.

A case of prolapsed rectum in a hog which was treated surgically, P. Gőnőh (Állatorvos Lapok, 32 (1909), No. 46, p. 566; abs. in Berlin. Tierärztl. Wehnschr., 27 (1911), No. 8, p. 134).—A case is reported in which a rectal prolapse extending about 20 cm. outward was successfully treated by resecting the necrosed section of the gut.

Hog cholera and state vaccination, J. F. Stanford (Arkansas Sta. Circ. 12, pp. 8, figs. 5).—This is a popular account of hog cholera and its prevention through the use of hyperimmune serum. An appropriation of $2,000 made possible the preparation and distribution of antihog-cholera serum in Arkansas. The work was taken up by the department of bacteriology and animal pathology in cooperation with this Department during the spring of 1907 and continued until July 1, 1909, when it was transferred to the department of veterinary science of the college.

The significance of the microscopic blood examination for the infectious diseases which occur in the horse, with particular reference to diagnosis and prognosis, F. Berger (Die Bedeutung der mikroskopischen Blutuntersuchung bei den Infektionskrankheiten des Pferdes in bezug auf Diagnose und Prognose. Inaug. Diss., Univ. Bern, 1909, pp. 87, pl. 1).—After reviewing the existing work on the histology, physiology, and pathohistology of the blood of the horse, the author details his own results with horses affected with strangles and influenza.

It is shown that in equine influenza a hyperleucocytosis is usually present, but that the amount has no relation to the degree or severity of the disease. No parallel could be noted between the leucocytosis and the height of the fever. It was further noted that the percentage of neutrophils is changed, the polymorphonuclears increasing at the expense of the mononuclears, and the eosinophils disappearing at the height of the disease but beginning to return when the inflammatory process begins to subside. In strangles at its initiation a very slight leucocytosis is present, but this increases when the glands begin to swell and remains high until the abscess has fully formed, after which the leucocytes begin to fall to the normal amount again. A parallel exists between the leucocytosis and abscess formation. If a new swelling is produced, then the leucocyte content begins to rise anew and goes through the usual cycle.

The above hematological findings are compared with the results obtained by the author with normal animals.

The use of Gans’ polyvalent serum against strangles, A. Schwarz (Die Anwendung von polyvalentem Drusserum Gans. Inaug. Diss., Univ. Bern, 1909, pp. 87).—As a protective vaccination with foals this serum in the hands of the author gave good results.

In regard to the curative value of the serum, he first points out that other conditions which are accompanied by swollen glands may be easily mistaken for strangles, but he considers a case strangles only when purulent coalescence of the glands has taken place. If a marked enlargement of the throat glands is present, or if they have gone on to abscess formation, the serum, even if injected repeatedly, will not influence the course of the disease and will seldom prevent the occurrence of complications. In about 20 per cent of the cases
treated the author was able to note that on the day following the injection a
recession of from 0.4 to 1.8° C, in the temperature took place and that the nasal
flow was checked, but 2 days later the temperature resumed its high level again,
the nasal secretion took on its original character, and the process in the glands
went on.

Accessory thyroid tissue within the pericardium of the dog, J. L. Swarts
I).—In 21 of the 24 animals showing pericardial thyroids, the structure of these
bodies corresponded almost identically with the structure of the thyroid glands
of the same animal. The exceptions were two colloid goiter dogs and one
animal with hyperplastic thyroid, all of which showed normal pericardial
thyroids.

In regard to the refraction of the dog’s eye, R. Boden (Über den Refrac-
tionszustand des Hundaugees. Inaug. Diss., Univ. Bern, 1909, pp. 52, pl. 1,
figs. 4).—The eyes were examined of 100 dogs, consisting of various breeds
and ages, and of both sexes.

The results show that the average dog is myopic, this being on the average
equivalent to 3 diopters. The limits found were from 1.5 to 6 diopters. The
various methods for determining the refraction of the eye are discussed, but
for dogs the author considers Schmidt-Rimpler’s method to be the best.

Bacillary white diarrhea of young chicks, L. F. Rettinger (Abs. in Science,
n. ser., 33 (1911), No. 849, pp. 547, 548).—A continuation of investigations
previously noted (E. S. R., 22, p. 489). The author reports having found
Bacterium pullorum present in the ovary of a pullet less than 8 months of age
and one of the survivors of an infected flock, thus showing the laying hen to
be a bacterium carrier.

On a possible cause of pneumo-enteritis in the red grouse (Lagopus
pp. 46, 47).—The authors state that of a lot of 40 grouse chicks 17 died between
the ages of 4 to 6 weeks. Upon examination the birds were found to be
suffering from coccidiosis, the parasites (Entemia [Coccidium] axium) occur-
ing especially in the duodenum and ceca. As many of the young birds also
presented symptoms of pneumonia, the lungs, trachea, and bronchi of the
birds were carefully examined.

Coccidian oöcysts were found in the trachea, bronchi, and bronchioles. “In-
side these oöcysts the processes of formation of the four sporoblasts were
sometimes found to be going on. The oöcysts were probably acquired by the
mouth, and a few of them, instead of passing directly down the digestive
tract, as is usual, may have found their way, via the glottis, into the trachea
and bronchioles.”

RURAL ECONOMICS.

Banking and its relations to our agricultural interests, J. R. Mulvane
the board of directors of the Bank of Topeka, the president of the bank dis-
cusses the economic relations between banking and farming, showing their
interdependence and necessary correlation.

Loans on improved agricultural lands (U. S. House Representatives, Hear-
ing Before Com. on Banking and Currency, 1911, pp. 3).—This is the report of
a hearing before the House Committee on Banking and Currency on a bill
authorizing a national banking association to make loans upon improved agri-
cultural land from “any portion of its funds not exceeding two-thirds of the
amount of its deposits not subject to check.”
RURAL ECONOMICS.

293

As an argument in favor of the bill it was stated that in 40 national banks in one congressional district in Minnesota there were deposits amounting to $10,662,564.78, of which $6,446,715.01 are time deposits not subject to check.

Credit banks in France (Jour. Bd. Agr. [London], 17 (1911), No. 16, pp. 844–849).—The article discusses the actual workings of credit banks in France as provided for by the act of March, 1899.

The progress made is regarded by the French ministry of agriculture as encouraging and it is anticipated that in the course of time such banks will be established in every district of any importance. The following figures show the progress made from 1900 to 1909:

**Status of credit banks in France in 1900 and 1909.**

By the act of March 19, 1910, loans for short periods have been extended and made applicable to “small holdings” for periods as long as 15 years with interest usually at 2 per cent per annum. “The loans are made through the local and district banks, the money being furnished by the State free of interest.”

The different forms of rural cooperative [credit] societies (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intel., 1 (1910), No. 1, pp. 284–301).—This article deals with the present state of agricultural cooperation and credit in Italy as administered by “popular” banks, rural banks, and other institutions.

The “popular” banks were formed in the towns and are especially adapted to serve the great industrial interests, the agricultural middle classes, and tenant farmers, while rural banks have for their principal object the provision of capital to the small freeholders, farmers, and metayers. The “popular” banks in 1870 numbered about 50, with a total capital of 15,000,000 francs, and in 1909 their number was 525, with a total capital of 250,000,000 francs. The rural banks have no initial capital, but receive savings deposits, and when these are not sufficient they borrow from other banks or private individuals. They deal only with their members and have two kinds of loans, one extending over a period of not more than 2 years and the other extending even to 10 years.

The other institutions engaged in agricultural credit have a different historical origin from that of the “popular” banks and rural banks, but the economic principles involved are the same. They make loans for the benefit of agriculture generally, and for encouraging and developing cooperative productive societies, cooperative distributing societies, credit societies for the benefit of laborers, artisans, clerks, small freeholders, etc.

The difficulties of the agricultural bank of Egypt, H. W. Wolff (Economist, 71 (1910), No. 3513, pp. 1299, 1369).—While the author recognizes the very valuable service the agricultural bank has rendered to its country, he points out that “the cause of the trouble which has overtaken the bank is undoubtedly to be found in its system,” which resulted (1) in placing heavy indebtedness on the land for unproductive and unremunerative purposes, and (2) in the too free lending of money on the increased market value of land when there was not a corresponding increase in its productive value. “The
first mistake made in the organization of the agricultural bank of Egypt is, that under it, real credit, secured by mortgage, is made to serve the purpose of personal, for the provision of working capital for a limited time."

A model cooperative marketing association (Farmer, 29 (1911), No. 17, pp. 613, 617).—This article describes the working of the Producers' Cooperative Marketing Association and shows what it is doing in northeast Minnesota in bringing producer and consumer into closer touch with each other and eliminating the speculator.

The principal market is at Duluth, where the association has market places and warehouses supervised by a board of directors and a manager who have authority to grade or reject any produce sent for disposal. As a rule, produce is sold direct to the dealer. A charge of 10 per cent is deducted from receipts of produce to pay for expenses of handling and selling. The market has only been in operation a short time but the amount of business transacted for the first six months amounted to over $30,000.

It is stated that attempts to weaken the association by occasionally offering extra prices for farm produce have been wholly unsuccessful. Members of the association are planting in most cases five times as much land to garden produce as in former years. It is suggested that the plan can easily be carried out in other localities.

[Agricultural cooperative societies in Germany] (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intell., 2 (1911), No. 2, pp. 17–37).—At the close of 1910 the agricultural cooperative societies in Germany numbered 24,175, including 94 central societies, 15,616 rural credit banks, 2,265 societies for the purchase and sale of supplies, 3,213 creameries, 151 societies for the sale of milk, and 2,836 other societies. Further statistics as to cooperative societies are given and the work of the federations and central institutions of the cooperative societies and of the large agricultural associations is presented and discussed.

New statistics of agricultural cooperation in Austria (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intell., 2 (1911), No. 2, pp. 38–76).—Data are presented as to agricultural cooperation in Austria, including statistics as to the cooperative credit societies, warehouses, creameries, and federations of cooperative societies.

At the end of 1907 Raiffeisen banks numbered 5,880 with 752,666 members. The total amount paid up on shares was 9,096,743 crowns, and the amount of loans granted by the banks at the end of the year was 428,242,262 crowns. The amount of saving deposits and deposits in current accounts averages 94,612 crowns per bank and 767 crowns per member, indicating a considerable influence of these banks in inducing thrift among the rural population.

Tables and illustrations accompanied by discussions explain the work and success of many other cooperative organizations.

Insurance against accidents in agricultural labor and Signor Luzzatti's bill on the subject (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intell., 2 (1911), No. 2, pp. 151–168).—This article discusses some of the important features of the present law in Italy upon accidents in labor generally (E. S. R., 21, p. 492): the bill proposed by A. Conti on the obligatory insurance of peasant laborers against accidents in their labor (E. S. R., 22, p. 91); and the bill presented by Senator Luzzatti to the Italian Senate December 5, 1910. The fundamental points of discussion have been classified as follows: (a) Limits of the application of the law; (b) systems of compensation; (c) persons charged with the cost and apportionment of the cost of insurance; and (d) organization of insurance.
Abstract of foreign labor statistics (Ibid. Trade [Gl. Brit.], Abs. Foreign. Labor Statis., 4 (1911), pp. 22-25, 30, 31, 34, 36, 80, 81, 98, 114-121, 280, 286-288, 290-292, 300-302, 365, 366, 308, 310, 350).—Statistical data dealing with labor in the United States and foreign countries are presented, showing the average yearly, monthly, and daily wages of all classes of agricultural laborers, together with tables showing the number of agricultural credit societies, and the capital, membership, loans, and other profits relating to them, and also tables as to accident insurance among agricultural laborers in several foreign countries.

Agricultural labor in the United Kingdom, C. R. Loo (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 17, pp. 260, 261).—This is a partial abstract of a report issued by the British board of trade relative to wages and conditions of employment of agricultural laborers in the United Kingdom.

The total average weekly wage of adult male laborers of all classes regularly employed in England is shown to be $4.46; in Wales and Monmouthshire $4.38; in Scotland $4.76; and in Ireland $2.74.

The different classes of workmen are classified as ordinary laborers, horsemen, cattlemen, and shepherds, and the average wage of each is reported. It is pointed out that these earnings will compare favorably with those in industrial towns when the greater cost of living is taken into account. A much higher wage is paid in Scotland in every class than in any of the other parts of the British Islands. Little increase is shown in the average earnings of any of the agricultural laborers for the last few years.

Wages of agricultural workmen, P. McConnell (Dairy, 23 (1911), No. 265, p. 11).—The data given in this article are noted above.

Wages and prices of commodities (U. S. Senate, Hearings Before Select Com. on Wages and Commodities, 1919, vols. 1, pp. 1-655; 2, pp. 659-875; Digest, pp. XCV).—This is a report of the hearings before the Select Committee of the United States Senate to investigate the wages paid by different industries and the prices of both raw and manufactured materials. Testimony is given by men experienced in the various methods of production and distribution of those commodities which go to make up the cost of living and the basis upon which wages are generally determined. Data are given showing the wages paid farm hands for a period of years, the prices paid for farming implements and supplies, the actual cost of producing various farm products, and the prices of such products on specified dates.

Crop Reporter (U. S. Dept. Agr., Bur. Statis. Crop Reporter, 13 (1911), No. 5, pp. 33-49).—Statistics and notes are given upon the condition of crops May 1, 1911, with comparisons with previous years, farm value and range of prices of important crops and products, cost of producing wheat in 1909, acreage and yield of cotton in 1910, temperature and precipitation statistics, monthly receipts and stocks of eggs and poultry in the principal cities of the United States, and other data.

Agricultural statistics, 1910 (Bd. Agr. and Fisheries [London], Agr. Statis., 45 (1910), Nos. 1, pp. 199; 2, pp. 101-190).—The report contains tables of agri-
cultural statistics showing the total acreage and yield per acre of each of the principal crops in the United Kingdom in each year from 1895 to 1910 inclusive, together with live stock returns and prices of agricultural products.

Summary of commonwealth production statistics, for the years 1901 to 1909, G. H. Knibbs (Commonwealth Bar. Census and Statist. Melbourne, Prod. Bul. 5, pp. 128).—This bulletin contains official statistics pertaining to the total yield, average yield, value, wholesale prices, etc., of the principal agricultural crops and farmyard produce in the several states of the commonwealth of Australia for the season 1909-10, and in addition gives a summary of similar statistics for the years 1901 to 1909 inclusive.

AGRICULTURAL EDUCATION.

The rural school as a community center (Tenth Yearbook Nat. Soc. Study Ed., 1911, pt. 2, pp. 75).—This, the Tenth Yearbook of the National Society for the Study of Education, includes the following contributions:

Community work in the agricultural high school, B. H. Crocheron (pp. 9-16).—A description is given of the extension work of the consolidated agricultural high school at Philopolis, Md., this including evening lectures in winter for farmers, short courses once a month for farmers' wives, a literary society for young people, meetings for rural school teachers, and summer problems at home for the high school boys.

The district schools in a county as educational and social centers, Jessie Field (pp. 17-19).—The need of maintaining the thoroughness and efficiency of the general work of the district schools is emphasized. At the same time the need is pointed out of connecting this work with the home interests of the pupil, the agricultural problems through boys' clubs and encampments and the home-making problems through similar work with the girls.

Rural-school extension through boys' and girls' agricultural clubs, F. W. Howe (pp. 20-28).—A review is given of the development and present status of the boys' agricultural club movement in the United States, with descriptions of some of its more striking and interesting phases. The influence of this work is summarized in its bearing upon the individual and the community at large.

Relation of rural school to better housekeeping, E. C. Bishop (pp. 29-33).—The author describes the work done by the state department of education and the college of agriculture in Nebraska in enlisting the interest and cooperation of public school teachers in the developing of sewing and cooking contests among school girls. The work in these contests was done at home and the articles made were exhibited at school, township, county, and state exhibitions.

Rural-school libraries, A. B. Graham (pp. 34-43).—The development of the rural-school library is outlined and its functions discussed, as are also such topics as selecting the books, means of raising funds, and the care of books. A suggestive library catalogue is given.

The rural school as a means of developing an appreciation of art (indoor and outdoor), O. J. Kern (pp. 44-52).—This paper is essentially a review of the 12 years' work of its author for better school buildings and more artistic school surroundings and indoor decorations in Winnebago County, Ill.

Organized recreation in rural schools, M. T. Scudder (pp. 53-59).—Data are given concerning some practical experiments in organizing rural school recreation in country schools in New York State.

The general problem of the relation of the rural school to community needs—a summary, B. M. Davis (pp. 60-63).—In this article the more important features of the preceding chapters are summarized and some related data are given.
Bibliographies prepared by the United States Bureau of Education and by the editor of the yearbook are appended.

Agricultural education, J. Macdonald (In _Stephen's Book of the Farm_, Edinburgh and London, 1908, vol. 1, 5, ed., rev., pp. 30–37).—This is a brief review of the development of agricultural education in Great Britain, in which are considered the older teaching centers, the modern agricultural colleges in England and Wales, the cooperation of county councils, the agricultural colleges in Scotland, the growing appreciation of agricultural education, aid to agricultural education by agricultural societies, and agricultural education in Ireland.

Indian boarding schools and agricultural education, L. Chubbuck ([Washington: Gov't.], 1911, pp. 5).—In this account, printed for the use of the House Committee on Indian Affairs, a summary is given of the work that is being done by the United States in the maintenance of a system of schools for Indian children. There are two classes of schools, day and boarding. The day schools, of which there are at least 150, are located on the reservations and may be regarded as miniature farm schools. The boarding schools are divided into two classes, those located on the reservations and those that are not. The boarding schools are, in theory, distinctively industrial in the direction of agriculture.

Agriculture in the public schools, L. S. Ivins (Lebanon, Ohio, [1909] pp. 156, pls. 8).—The object of this book is to furnish a guide for teachers in the rural schools who are expecting to prepare a course of study that will include the subjects of nature study and elementary agriculture. It also furnishes helpful suggestions on parents' meetings, public displays of school work, corn, potato, and vegetable growing contests, and home, rural, and city school flower gardens. Courses of study prepared by the state department of education of Ohio are given for third grade high schools (two-year course), second grade high schools (three-year course), and first grade high schools (four-year course).

Agriculture for schools of the Pacific slope, E. W. Hilgard and W. J. V. Osterhout (New York, 1910, pp. XIX+428, figs. 269).—This book covers a great many topics in an elementary way and is intended for use in parts of the humid as well as in the entire arid region. About two-thirds of its space is devoted to such subjects as plant needs, how the leaf gets food from the air, plant propagation and improvement, the influence of surroundings on the structure of plants, and the foes, friends, and diseases of plants. The various field crops follow and brief consideration is given to animal physiology and the various farm animals.

Some agricultural projects for elementary schools (Bul. Bd. Ed., Mass., 1911, No. 1, pp. 53, figs. 25).—This manual is divided into four parts: Directions for conducting 14 projects in farming, suggestions for garden work, 12 laboratory exercises, and collateral work which shows how letter writing, cooking, geography, arithmetic, drawing, and themes may be taught with an agricultural point of view.

Practical agriculture for rural schools, A. B. Graham (Agr. Col. Ext. Bul. [Ohio State Univ.], 6 (1911), No. 6, pp. 15, figs. 22).—This bulletin contains suggestions to teachers for conducting experiments with growing crops, making observations and collections, and identifying specimens. These are followed by lists of helpful books, bulletins, and other publications.

Southern field crops (exclusive of forage plants). J. F. Duggar (New York, 1911, pp. XXVII+579, figs. 222).—This book adds one more to the Rural Textbook Series edited by L. H. Bailey. The author had in mind in the preparation of this text the needs of two classes of individuals: "Students desiring a full and practical, yet logical and pedagogical treatment of the staple crops of the
South, and farmers seeking a simple presentation of the scientific principles underlying agriculture, together with a condensed statement of the results of recent experiments and experience.” The book is intended especially for high schools and normal schools, and when so used the author recommends that all the matter printed in small type and all technical names in parentheses be omitted. It is also intended to serve as an outline for college students. Eleven chapters are devoted to cotton, eight to corn, and one to each of the other important field crops of the South. Forage crops are omitted.

The type of teaching method presented is one that sends the learner directly to the plant in the field, to make careful observations from the tip of the root to tip of top. The treatment of wheat, which is typical of that given to all the crops considered, is in outline as follows: (1) Structure and composition, including roots, stems, leaves, pollination, the spike and the spikelets, the grain, and composition; (2) species and varieties, including the winter wheats of the cotton belt, the most productive varieties, means of distinguishing varieties, qualities desired in varieties for the South, and the improvement of varieties; (3) the kind of soils, the place in the rotation, and the fertilization of wheat; (4) cultural methods as to the preparation of land, when to sow, drilling v. broadcast sowing, and large v. medium and small seed; (5) harvesting; and (6) the enemies of wheat. Laboratory exercises and references to literature are furnished at the close of each chapter.

**Boys’ and girls’ potato and corn primer** (Mass. Agr. Col., Dept. Agr. Ed. Circ. 12, 1911, pp. 8).—Directions are given for the culture of potatoes and corn. References for the further study of each are added.

**The potato experimenter’s primer** (Mass. Agr. Col., Dept. Agr. Ed. Circ. 13, 1911, pp. 8).—The primer is intended for use by a boys’ potato culture club. It contains directions for making 5 experiments in potato growing, such as testing (1) the comparative value of different tubers, (2) the value of treatment for scab, (3) the effect of cutting potatoes into large and small pieces, (4) the best depth for planting, and (5) the difference between the product of large and small potatoes.

Our conebeaters and evergreens, C. H. Goetz (Agr. Col. Ext. Bul. [Ohio State Univ.], 6 (1910), No. 4, pp. 16, figs. 17).—Lessons are outlined which are intended to give school children an opportunity to become better acquainted with a few of the more common cone-bearing and evergreen trees.

**Forests of New York,** G. M. Wiley (N. Y. State Ed. Dept., Arbor Day Ann., 1911, pp. 53, pl. 1, figs. 31).—Outlines are given on the teaching of forestry along with the geography, agriculture, civics, and physical geography. A list of postgraduate and undergraduate schools of forestry as well as a reference list of forestry books is included.

**Alabama bird day book** (Montgomery, Ala.: Dept. of Game and Fish, 1911, pp. 60, pl. 11).—The material in this pamphlet was prepared with a view to assisting teachers in celebrating bird day by a study of the principal birds to be found in Alabama. A suggestive program is given.

**Reading list on birds and bird study** (Buffalo: Grosvenor Library, 1909, pp. 15).—This is a selected list of books and magazine articles of interest to those interested in nature study and out-of-door life. The list covers, among others, such subjects as bird study in the school, flight and migrations of birds, photographing birds, and bird protection.

Farm and home mechanics, some things that every boy should know how to do and hence should learn to do in school (U. S. Dept. Int., Off. Indian Aff. [Pub.], 1911, pp. 48, pl. 5, figs. 28).—The purpose of this manual is to set forth the results of practical experience in the work of instruction in the Indian schools. A suggestive list is given containing a number of “common articles
that have to be made for every home and on every farm, together with a number of processes with which every boy should be familiar." Line drawings illustrate the details of the more difficult articles.

Farm accounting and business methods, J. A. Bexell (Springfield, Mass., 1911, pp. 161, figs. 2, dgm. 1).—This is a textbook for students in agriculture and a manual for home study. It is divided into four parts, namely, financial accounts, cost accounts and special records, business organizations, and useful tables.

Lessons in farm accounting and business methods, J. A. Bexell (Springfield, Mass., 1911, pp. 27).—This is a syllabus of instruction sheets for use in connection with the above-named textbook. A loose leaf book accompanies the syllabus and furnishes models for keeping the cash book, inventories, personal accounts, statements, household accounts, and special records such as a milk record, a feed record, a daily labor record, a stock record, a breeding record, and a sales record.

A pioneer's experience in school gardens, J. W. Jones (Jour. Ed. [Boston], 73 (1911), No. 1), pp. 377–379, dgm. 1).—As a remedy for eight difficulties which beset a successful school garden, the sections pita system, which combines individual work with community work and responsibility, is recommended.

Annual report, New York City branch of the National Plant, Flower and Fruit Guild (Nat. Plant, Flower and Fruit Guild, N. Y. City, Ann. Rpt., 14 (1910), pp. 28, figs. 5).—One of the features of this report is an account of the maintenance of a children's farm garden in the heart of one of the most congested sections of the city.

Bibliography of science teaching (U. S. Bur. Ed. Bul., 1911, No. 1, pp. 27).—Under the subject of biology this takes up (1) articles relating to the teaching of biology as a whole, (2) articles on general science with special bearing upon biological subjects, (3) botany, and (4) zoology. It also deals with chemistry, geography, mathematics, nature study, and physics.

**MISCELLANEOUS.**

Report of the director for the year ending June 30, 1910, F. B. Mumford (Missouri Sta. Bul. 96, pp. 603–624, fig. 1).—This contains the organization list of the station, a report of the director summarizing the various activities of the station during the year, lists of exchanges and donations, and a financial statement for the Federal funds for the fiscal year ended June 30, 1910.

**Twenty-first Annual Report of New Mexico Station, 1910** (New Mexico Sta. Rpt. 1910, pp. 38).—This contains the organization list, a report of the director on the work, publications, and exchanges of the station, departmental reports on the various lines of station activities during the year, and a financial statement for the Federal funds for the fiscal year ended June 30, 1910. The report of the animal husbandry department is abstracted on page 272 of this issue, and a portion of that of the horticulturist on page 238.

**Thirty-second Annual Report of North Carolina Station, 1909** (North Carolina Sta. Rpt. 1909, pp. 151±117, figs. 124).—This contains the organization list, reports of the director and heads of departments, of which those of the poultryman and entomologist are abstracted elsewhere in this issue, a financial statement for the fiscal year ended June 30, 1909, numerous special articles abstracted elsewhere in this issue, and reprints of press bulletins entitled Selecting Seed Corn for Larger Yields, by C. B. Williams, The Apple Bitter Rot, by F. L. Stevens, Suppression of Terrapin Bugs, by R. I. Smith, and Spring Destruction of Terrapin Bugs, by R. I. Smith, and of Bulletins 200–204, previously noted.
NOTES.

Connecticut State Station.—Wilson H. Lee, of Orange, has been appointed a member of the board of control to succeed Charles M. Jarvis, resigned.

Delaware Station.—A. C. Whittier has resigned as assistant in nutrition in the Ohio Station to accept a position as research chemist.

Indiana Station.—G. G. Carter, inspector in the fertilizer and feeding stuffs control work, has resigned to accept a commercial position.

Kentucky University.—State Commissioner of Agriculture M. C. Rankin has announced that he will offer a scholarship of $100 in the agricultural course to the boy making the highest score in stock judging at the state fair. A similar amount is offered for prizes to the five college students making the best score.

New Jersey Stations.—Dr. B. H. A. Groth, plant physiologist in the College Station, has been granted a leave of absence for two months to study certain plant problems in Europe. Miner S. Macomber, an assistant chemist in the State Station, has resigned.

Ohio State University.—During the 10 months from July 1, 1910, to May 1, 1911, the agricultural extension department has conducted 79 agricultural extension schools for men and 75 domestic science schools for women, with an attendance of 17,000; 7 agricultural trains, on which lectures were given to 10,000 people; 125 orchard pruning and spraying demonstrations, with an attendance of 12,500; and other public meetings which bring the total number of people reached in these ways up to nearly 49,000. The department also made exhibits at 12 county fairs, at the National Corn Show, and the state apple show; made 123 school visits in the interest of agricultural and domestic art contests; and is conducting 200 boys’ corn contests and girls’ sewing and baking contests, with a membership of about 12,000. Monthly plate copy has been furnished to 148 county newspapers, 30,000 copies of the Agricultural College Extension Bulletin issued each month, 6 issues of the Farmers’ Reading Course Bulletin of 5,000 copies each prepared, and a like number of the Home Makers’ Reading Course Bulletin published, with supplements on corn, grain drills, poultry, dairying, drainage, pruning, spraying, and methods of teaching agriculture of from 10,000 to 25,000 copies each. In connection with these various activities the department has sent its representatives to numerous other meetings, and 6 instructors have visited farmers for the purpose of giving expert advice on farm matters. For the ensuing year there are already 91 applicants for agricultural extension schools in 66 counties, 6 agricultural trains for August, 1911, 3 agricultural trains at other times, 170 applicants from newspapers for plate copy, and 45 requests for exhibits at county fairs.

Oregon College.—Science notes that Juliet Greer, dean of the school of domestic science and art and professor of domestic science, has resigned to take effect July 1.

Washington College and Station.—W. S. Thornber, head of the department of horticulture, has resigned to engage in the supervision of horticultural work to be undertaken by two land improvement companies in Idaho. In connection with this work it is contemplated to carry on demonstration tests and to give instruction in a school of horticulture to be opened in 1912.

### IV CONTENTS.

The use of acid soils for raising seedlings of the Mayflower, Coville.................. 341
The small garden beautiful, Curtis................................................. 342
The suburban garden guide, Barnes.............................................. 342
Report of the Board of Metropolitan Park Commissioners......................... 342

#### FORESTRY.

The commercial woods of the United States and their uses, Surface....................... 342
The aspens: Their growth and management, Weigle and Frothingham...................... 342
Properties and uses of Douglas fir, Cline and Knapp.................................. 342
The Eucalyptus in Texas, Arbenz.................................................. 343
Gum and resin yielding plants, De Cordemoy......................................... 343
[Frubber investigations], Wilcox................................................... 343
Fustic wood: Its substitutes and adulterants, Sudworth and Mell....................... 343
Preservative treatment of poles, compiled by Kempfer.................................. 344
Fourth annual report on forest conditions in Ohio..................................... 344
Review of forest administration in British India, 1908-9, Bryant...................... 345
Forest administration in eastern Bengal and Assam, 1909-10, Monro et al................ 345
The need of afforestation in Great Britain and Ireland, Blaschek...................... 345
Suggestions for woodlot owners in Maine, Briscoe.................................... 345
The farmer's plantation, Mitchell.................................................. 345
Tree planting on the prairies of Manitoba, Saskatchewan, and Alberta, Ross........ 346
Our timber wealth and its conservation, Sutton....................................... 346
The Olympic National Forest: Its resources and their management, Burns.............. 346
Forest products of Canada, 1909.—Pulpwood, MacMillan................................ 346
Forest products of Canada, 1909.—Poles purchased, MacMillan......................... 346
Forest products of Canada, 1909.—Cross-ties purchased, MacMillan.................... 346
Forest products of Canada, 1909.—Cooperage boxes, and box shooks, MacMillan....... 347
Forest fires and railways, Campbell.............................................. 347

#### DISEASES OF PLANTS.

The dissemination of microscopic spores in the atmosphere, Bonnier.................... 347
Report of the mycologist for the year ending March 31, 1911, I, Rorer................. 347
Report on plant diseases for the year 1908-9, Schander................................. 347
Distribution of fungus diseases of plants in Russia during 1908, L'achevskii........... 347
Distribution of fungus diseases of plants in Russia during 1909, L'achevskii......... 348
Root diseases caused by Armillaria mellea, Lawrence................................... 348
Fungus diseases of ground nuts in the West Indies, South............................... 348
Rice disease caused by Ustilaginoidea graminicola, Essed.............................. 348
*Spongospora subterranea*, Osborn............................................... 348
Oospores of potato blight, Clinton.................................................. 349
A history of the damping-off disease of sugar-beet seedlings, Stiff...................... 349
On the history of the heart or dry rot of the sugar beet, Stilt........................ 349
[A fungus disease of the avocado], Higgins......................................... 349
The Panama disease, I, II, Essed.................................................................. 349
The Surinam disease; a condition of euhaptosis of the banana, Essed.................... 350
Diseases of the fig tree and fruit, Edgeron............................................ 350
The American gooseberry mildew order of 1909, Middleton.............................. 351
Influence of the stock on the susceptibility of the graft to grape mildew, Ravaz.... 351
Method of action of sulphur used in combating powdery mildew, Marcille............. 351
The black-rot disease of grapes, Reddick............................................ 351
The infection of the grape with Plasmopara viticola, Muller-Thurgau.................... 352
The summer spraying of peaches, Stewart.............................................. 352
Bitter plums, Sorauer.............................................................................. 353
A thread blight on Para rubber, camphor, etc., Bancroft................................ 353
A disease of seedlings of Pukauian oblongifolium, Bancroft............................. 353
A root gall of begonias, Schechmer..................................................... 353
Report of the department of botany, Brooks............................................ 353
Recent advances in our knowledge of lime sulphur, Stewart.............................. 353
Notes on a modified soda-Bordeaux mixture, Vermord and Dantony...................... 354
Use of Schweinfurt Paris green for controlling plant diseases, Hofman.............. 354

#### ECONOMIC ZOOLOGY—ENTOMOLOGY.

Atlas of zoogeography, Bartholomew, Clarke, and Grimshaw............................. 354
The mammals of the tenth edition of Linneus, Thomas................................... 355
On the common shrew mole (Scaupus aquaticus macrimum) in Illinois, Wood............ 355
CONTENTS.

Studies upon plague in ground squirrels, McCoy .......................... 355
Food of the woodpeckers of the United States, Beal ........................ 355
Index-catalogue of medical and veterinary zoology, Stiles and Hassall 356
Forty-first annual report of the Entomological Society of Ontario, 1910 356
Second report of the state entomologist, Gillette .......................... 356
Report of the entomologist, Fullaway ........................................ 356
Report of the department of entomology, O’Kane ............................ 356
Report of state entomologist and plant pathologist for 1910, Bentley 357
[Reports of the entomologist and assistant entomologist], Urich and Guppy 357
Insect pests in 1910, MacDougall ............................................. 357
Some local insects of economic importance, Navarro ....................... 357
[Control of citrus insects], Higgins .......................................... 357
[Two insect pests of the avocado], Higgins .................................. 358
Five important grape insects and their repression, Hall ................. 358
[Insect enemies of the mango], Higgins ...................................... 358
Insect enemies of the pecan, Chittenden .................................... 358
Cattle in Central America, Downing ........................................... 358
Termitite life in Ceylon, Escherich ............................................ 358
Studies of Mallophaga and Anoplura, Mjöberg .............................. 359
Experiments with cotton stainers, Robson ................................. 359
The white fly (Menodes civr), Mally ....................................... 359
The Aphididae of the vicinity of Hermannstadt, Henrich ................ 359
Danger of general spread of the gipsy and brown-tail moths, Marlatt 359
A new species of Lasioptera with observations on certain homologies, Felt 359
Some facts about malaria, Howard .......................................... 359
Remedies and preventive against mosquitoes, Howard .................... 359
Food habits of Megarhinus, Knab ............................................. 359
The papataci flies (Phlebotomus) of the Maltese Islands, Newstead ... 360
Preliminary report on the life histories of two species of Syrpoidea, Metcalf 360
The house fly, disease carrier, Howard ..................................... 360
Transmission of tuberculosis by flies, Jacob and Klopstock ............ 360
Lucilia sericata as a household pest, Morse ................................ 360
The parasites of the olive fly in Tunis, Marchal .......................... 360
The destruction of fleas by exposure to the sun, Cunningham .......... 360
Two species of cysticeroids from the rat flea, Nicoll and Minchin ... 361
The mechanism of transmission of Trypanosoma brucei by the rat flea, Strickland 361
Bees, Phillips ............................................................................ 361
The honey bee in Vermont, Beecher ......................................... 361
The treatment of bee diseases, Phillips ..................................... 361
Biological notes on Pimpla pomorum, Makrzecki ......................... 361
Gametogenesis of the gall fly, Neuroterus lenticulareus, II, Doncaster 361
Some parasites of Lasius fuliginosus, L. niger, and L. flavus, Crawley 362
A new sawfly of economic importance, Rohwer ............................ 362
Studies in the sawfly genus Hoplocampa, Rohwer ......................... 362
An insect injurious to spruce trees, Cockayne ............................. 362
The Colorado laws governing horticultural inspection .................. 362
A contribution to our knowledge of insecticides, McClintock et al 362
A further contribution to our knowledge of insecticides, McClintock et al 362
Hydrocyanic-acid gas fumigation in California of citrus trees, Woglum 363
The value of sodium cyanid for fumigation purposes, Woglum ......... 363
Killing rats and rat fleas by hydrocyanic-acid gas, Stevenson ......... 363
A fungicide and insecticide blower, Zacharewicz ......................... 363
Analysis of Paris green, 1910, Kellogg .................................... 363

FOODS—HUMAN NUTRITION.

The milling value of water-soaked wheat, Olson ............................ 364
On the chemical changes produced in flour by bleaching, Monier-Williams 364
Bleaching flour and the addition of so-called “improvers” to flour, Hamill 366
Presence of calcium sulphate in baking powder and self-raising flour, Hamill 367
The carbohydrates of lichens, algae, and related substances, Swartz 367
Preservation of horse meat by low temperature and its use, Costa and Mori 367
Do Paratyphoid-like bacteria occur in meat under normal conditions? Bongartz 368
Fish inspection, Cannella ....................................................... 368
Food-Inspection decisions ....................................................... 368
Notices of judgment .................................................................. 368
Official inspections .................................................................... 368

Note.—The price of Experiment Station Record is $1 per volume, and two volumes are issued annually. It may be purchased from the Superintendent of Documents, Washington, D. C., to whom all remittances should be made. The publications of the State experiment stations are distributed from the stations and not from the Department.
In weighing the advantages of a calling or a field of work the apparent returns and compensations naturally come in for prominent consideration along with the tastes and inclinations of the individual. This is true when a career is being selected or when a change of position or of occupation is contemplated. If the calling or the position is a commercial one, the standards of business will naturally weigh heavily, but if it is a scientific career, quite different standards and considerations should prevail, and as between the two spheres there are wide distinctions to be taken into account.

These distinctions and standards are not appreciated by the world at large and they are not always fully taken account of by either young men or those already engaged in scientific work. This is evident from the experience of men connected with our agricultural colleges and experiment stations. Too often the pecuniary consideration temporarily overshadows all others and the standards of business success shut out a just appreciation of very real compensations which should have large influence with the man of science. This turns young men from the field of teaching and investigation and leads to dissatisfaction and unrest among those engaged in it. Not infrequently men compare their work and its returns with those of a commercial or professional career, to its apparent disadvantage, because its special conditions and compensations are temporarily lost sight of. The opportunity for increased salary and the ultimate possibilities in business loom large in the horizon and lead even specially trained men to abandon a scientific career, often to their regret after a short experience.

Commercial and professional positions undoubtedly hold out larger material rewards to the men who are able to command them, and they probably always will. As a result there is a danger that the standards and rewards of the market place will fill an undue portion of the horizon of the young investigator, to the exclusion of other and no less important considerations. That this is the case with students in college is evidenced by the experience of the large universities, which have commented on the relatively small number who devote
themselves to scientific pursuits, and among those who attend our agricultural colleges the call to the farm or other agricultural pursuits and the opportunity which is now open deter all but the occasional student from advanced study.

"Scientific farming" has become a popular phrase and the appreciation of the man who can couple science with his farming or apply it to various branches of the agricultural industry has made a large and increasing demand. Those entering upon agricultural investigation are thus especially exposed to temptations to abandon their work, and particularly if they have not fully caught the spirit and the appeal of scientific work they are likely to be attracted or distracted by the financial returns of modern orcharding or special farming and long to see the results of their effort measured in bushels or tons or dollars of increase.

This is a matter of no little importance to the success of our agricultural institutions. The colleges must prepare men for the business and professional sides of agriculture, but somewhere and somehow bright, capable men must be had for the great and growing work of education and investigation. The inclination to enter it is partly temperamental and depends upon an outlook and a point of view which the colleges can do much to inculcate. If such a career can not hold out as large remuneration as some other callings, the other compensations of real worth deserve to be understood. It may be profitable, therefore, to consider some of the characteristics and distinctions of such a life work and its ability to satisfy the aspirations of men who are by nature attracted to it.

A scientific career is one of service to human welfare and advancement. It thus affords an opportunity to do the world's work and to take a vital part in the progress of civilization. Science and education are two of the great civilizing agencies of the world. The real force of this is beginning to be more widely appreciated. As a recent writer has said, "Science is the one great motive force of modern civilization on which all progress, all wealth, and even all existence increasingly depend."

The German mind realizes that the wealth and well-being of the Empire must ultimately depend on science and it expresses this feeling in the high position it accords to men of that calling. At every great state function in that country a prominent place is assigned to the representatives of pure and applied science.

Science guides judgment and reason and helps to interpret experience. Until we have science, reliance is placed on dexterity, experience, the results of repeated trials, many of them unsuccessful. In this way a purely empirical means is developed, a rule-of-thumb method, which knows not reason and is based on chance, except as it
follows the result of wisely judged experience. All experience rightly interpreted is helpful, but without the knowledge of the reason or the modifying causes and without the application of what is designated as the scientific spirit its interpretation is likely to be misleading and its generalizations erroneous or only half true. Hence the productive worker in science is helping to build the world's knowledge and his work is singularly one of public service.

Assuming that a scientific career as a teacher and investigator has been entered upon because of the appeal which it makes to the individual, the satisfaction which comes from its pursuit is one of its greatest compensations. It makes his life virile, purposeful, productive: it is a carrying out of an impulse which finds its reward in the satisfaction of a deep inward craving—a satisfaction entirely different in kind from that pride which the skilled worker takes in the performance of his task.

As Dr. Armsby has said, "A man may be at least a fairly efficient bricklayer or machinist or farmer or bookkeeper or Government clerk or follow successfully any one of a score of skilled trades without necessarily having any very special desire to do that particular thing rather than anything else. With the investigator it is different. His chief desire, if he be a true investigator, is not to do but to know—to penetrate behind the appearance of things in nature and learn their secret causes and complex interrelations."

To such a man a scientific career meets his tastes and his natural inclinations. It brings him into an atmosphere, an association, a freedom not found in business. The purpose and the spirit of work are distinctly different, as is the reward. The pleasure that comes in the pursuit of knowledge and its effective diffusion, and especially of knowledge which will find an application in the lives of men in our own generation, is of a different kind from that which comes of success in most other callings. The gratification which follows accomplishment for purely personal ends is not to be compared with it.

The chief interest of the investigator lies, as Prof. Cannon has recently pointed out, in the territory which has not been traversed. "Indeed, he is to be classed with explorers and pioneers. For such men the complacent contemplation of things accomplished is intolerable—they chafe under the routine of established ways, and find the satisfaction of life in adventures beyond the frontiers. . . . The satisfactions of a life devoted to investigation, like the satisfactions of other careers, arise from the profitable use of one's powers. The employment of these powers is perfect freedom, and the immeasurably important results that flow therefrom render the satisfaction of productive scholarship especially keen. . . .

---

*Science, n. ser., 34 (1911), No. 864, p. 66.
"Because every discovery becomes the basis for further discovery, the imagination of the investigator is constantly stimulated. New facts suggest in turn other facts, and point to unexpected relations between things that have long been known. These excursions of the imagination offer repeated suggestions for fresh adventure, the look is always forward to what may be seen when the next step is taken. The chance of beholding unsuspected wonders, or the possibility of finding that something imagined is really true, is a constant incitement to further search, and furnishes the zest and interest which are among the best rewards of the investigator."

The permanent character of scientific work is a large element in the satisfaction which comes from its pursuit. It is not merely the production of something ephemeral, of transient value or use; but it aims at the discovery or application of facts which are lasting. To quote Prof. Cannon again: "The value of labor that brings a revelation of new knowledge does not cease with the day; it remains as a permanent acquisition for the race. There is really great satisfaction to the investigator in this thought of the durable results of the perishable years."

A scientific fact is a permanent product, and the steps by which it is attained are only secondary in value because they lead to a broader and more permanent understanding of the subject. Even though the results do not lead directly to generalizations the work is worth while if well done. What Huxley designated as "the slaying of a beautiful hypothesis by an ugly fact," while often disheartening to the investigator, is not without value in clearing the way. Many negative or inconclusive results are usually necessary to the establishment of a truth. Its attainment is the highest and most enduring product of man's activity.

The service of the man of science is founded on individual effort. It is not merely a drifting along from day to day, doing the routine duties that come to hand, or working as a part of a big system in which the individual is well-nigh lost sight of. It is objective individual effort, which puts a man to the test and brings out the best there is in him. It taxes his knowledge, his ingenuity, his resourcefulness, his perseverance. It is bounded by no limitations except the initiative and industry and ability of the individual.

The position to which a man may advance in his science and its applications is determined only by himself, if the opportunity be given him, and at this time the opportunity will be likely to materialize if the qualities are present to demand it. A great variety of positions varying in grade and in the opportunity they afford are now presented in this country, and unfilled places await men who shall be qualified to take them. This gives an unusual inspiration and incentive to such a career.
Then there is freedom for a man to work out his problem in his own way and largely in his own time. There is no time limit fixed for a project, and no prodding or impatience if it is evident that progress is being made; and there is large latitude for the exercise of individual initiative and judgment. The case is quite different with an industrial specialist. There time is money, and results must be forthcoming to justify the salary and other expense. The keen competition of the commercial world enters into the life of its experts.

There is freedom also in the use of the results of a man's studies, upon which he may build his reputation, his greatest asset. In the case of the industrial expert the product of his work is for the use of the business, and is usually not at his disposal to publish abroad or report to his colleagues in science. This detracts to that extent from the satisfaction which comes of accomplishment, and cloaks the personal element.

Again, the associations and conditions of business life are far different from those in a scientific institution. This is exemplified in many ways and to a degree little realized by men who have followed a scientific career closely. The traditions and standards are different, as are the aims and methods. The whole atmosphere and spirit and the appeal are so different that men rarely shift readily from one sphere of work to the other.

Consideration of the individual is much greater in a scientific institution than in business. The large majority of men in industrial pursuits must work under direction, and take orders from those higher in authority. The opportunity for a specialist to gratify his inclinations and to follow out a special inquiry or test an idea are limited. Permanency in position depends largely on the business point of view.

Appreciation is a large element in the satisfaction which comes of a scientific career. To have one's work understood and recognized is no small part of the reward. Although the reward of the world's praise is no proper part of the aim of the true investigator, such recognition and appreciation gives encouragement which is helpful to most men in maintaining their zeal. And it is a very real reward, for it is of some consequence to win the world's respect and approval for tasks well performed—for a position built upon substantial worth.

Recognition comes first from a man's colleagues and fellow workers in science, who are able to understand the significance of his accomplishment. It is shared by the authorities of his institution, from whom he will derive much of his pride and satisfaction. The latter owe him their encouragement and sympathetic support. The publication of his work is the medium for a wider recognition which is his highest aim—the founding of a reputation which shall endure.
Public appreciation usually comes later, and is really of secondary importance except as it leads to providing the means and opportunity for continuing the researches. The man who caters to it is apt to find himself looking to the renown rather than to the acquiring of knowledge. The introduction of such a motive is a distraction and may readily lead to wrong ideas of success and reward. It is rarely definite or comprehensive unless the character of the work is popular. Too much must not be expected of it. The public is not discriminating, and it may lose sight of the identity of the real author for a time, for the results of scientific work filter down to it slowly and through various intermediate steps. To the average man the fact is more important than the author or demonstrator of it. But more and more the public appreciates the importance of such service in a broad way, and recognizes the class of men engaged in it. It expresses this in an attitude of respect and confidence, and in a position which it involuntarily accords them.

If the man who makes two blades of grass grow where one grew before is a public benefactor, as has long been accepted, the men who are devoting their lives to securing greater agricultural efficiency in all directions compose a band of workers for the world's advancement who will some day be regarded as meriting monuments and memorials quite as much as military heroes, because their work comes close to the public generally and touches their daily lives at so many vital points.

Another compensation is the opportunity which is given for leadership. The conspicuously great man is a product of opportunity. This makes the outlook in the field of agriculture exceptionally imposing. The places of most of the great men of the past are not filled and will not be. Our conditions are changing; the level upon which the average man of to-day lives is fairly high. The specialist has become the successful worker of the day. The great industry of agriculture, so long neglected by the sciences, affords a splendid theater for his effort. There are no more live or far-reaching questions to-day than those which turn about that art, and already the man of science is appealed to with confidence in his ability. The scientific method probably finds no more extensive and important application to social problems at the present time than in this field. The opportunity for leadership which will bring reputation in science and in a national sense is unexcelled.

The relative permanency and stability of position is another element to be considered. Positions in public institutions are each year becoming more permanent in character, and the degree of uncertainty is less for the successful worker than in most other callings. This enables a man to live his life free from worry, and plan for the future with reasonable assurance. While the pension system is not yet
EDITORIAL.

307

general, the demands on a man by his institution are usually decreased with advancing years, and there is leniency and leave of absence in case of illness. Some provision for retirement without entire loss of salary is now available in merited cases at a large proportion of the public institutions.

And what shall be said of the opportunity for gratifying cultured tastes, and for association and sympathetic relations with men of similar tastes and standards and aims in life? These are very real incidents to a scientific career, as are membership in scientific societies, the meeting with fellow workers in all branches of science, and the ability to command a place among them.

The capital of the man of science is his education, his ability, and his standing, which no financial panic can wrest from him. His stock in trade is independent of business conditions or fluctuation in values, and rarely fails to find a market. Competition and the struggle for advantage and supremacy are no part of his activity. Personality is its dominant element.

His work is congenial, stimulating, and inspiring to himself and to others; it is not colored by personal interest or considerations, but is unselfish and public spirited. It is broadening, elevating, life-giving. It enables him to live an honorable, respected, and satisfying life of usefulness, among congenial associates and surroundings which add much to the pleasures of his daily life. The opportunity which is afforded is at once a man's duty and in a measure his reward, for it is the fulfillment of his ideals.

This is not to say that he should not be well paid—better paid than is very often the case considering the standards of his living, what is expected of him, and his natural ambitions for his family. The value of his service to the community is far out of proportion to the salary he receives or can usually expect to attain. He is usually dependent upon it. He is completely out of touch with means of "making" money. He has isolated himself from such connections and has devoted his life to other ends, public in their final reach.

To him money is not the aim of life—merely a means of providing its necessities and advantages. He need not look to it either as a means of attaining position in the community, for that is accorded him. But beyond the mere necessities of life, salary is to some extent the world's measure of a man's success and attainment, and to him it is a very tangible evidence of appreciation.

The aspirations of the normal man have been summed up by the late President Canfield under three heads: To live, to be a man among men, and to do that which will endure. His words may be quoted here.

4496°—No. 4—11—2
"First, to live; not merely to exist. Almost anyone can exist in these days, and especially in this country of ours. Mere existence is so easy and so common that a failure to secure this becomes noteworthy; the starvation of a single person in a population of nearly eighty millions becomes at once such an item of news that it is wired from one end of the country to the other and is commented upon by the daily press under special headlines. But the normal man desires something more than existence. He desires to live, in the sense that he wishes his fair share of those things which give color and meaning to his century. . . . In a word, he must be able to live as a breadwinner and husband and father and good citizen ought to live. This is not only his own right, but the rightful demand of the welfare of the entire community.

"Second, to be a man among men. He is not to be content while he remains unrecognized and unknown. He is not simply a unit to be counted, but a man to be weighed and reckoned with. He wishes to stand shoulder to shoulder with his fellows, to look level in the eyes of other men with a sense of equality and power, to feel that his experience and his observation and his resulting opinions are of value to the world and the value is recognized, that men hesitate to as to certain undertakings until they know where he stands. He will not admit that he is only a fraction of a man, but insists that he is at least one of the full integers which make up the sum of life. He is not to be a flint that never strikes fire. His nature desires and demands the esteem and the regard and even the affection of his fellows.

"Third, to do that which will endure. He will have no part in oblivion; he is unwilling to be forgotten; he can not abide the thought that his work is to perish, that all that to which he has given his time and strength and thought and power comes to an end simply because his body dies. He wishes to project his temper and his purpose and his plans into the future, to find in this way and even here the beginnings of immortality, so to labor that at least a part of his finite product may be worthy to be woven in and in with the divine plan and thus become lasting and infinite."

This is a high and a noble ideal. It appeals to the best there is in man. But who shall say that a scientific career in the field of agriculture does not open the way to the realization of these three controlling desires in a high degree? To one with the proper temperament such a career is a challenge to the supreme use of all his powers—to his imagination, his ingenuity, his patience and enthusiasm, and to his spirit of disinterested service.
RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

An introduction to bacteriological and enzym chemistry, G. J. Fowler (London, 1911, pp. 11 + 328, pls. 4, figs. 28).—The chapters in this book are as follows: The characteristics of chemical action in living matter; outlines of bacteriological technique; some leading conceptions in organic chemistry; space-isomerism and the chemistry of the sugars; the hydrolysis of starch by amylase; the conditions of formation of amylase in the living cell; invertase and maltase; the alcoholic fermentation of grape sugar; the acid fermentation of alcohols and carbohydrates: the fermentation of cellulose and allied bodies; miscellaneous fermentations, fat-splitting enzymes, oxidases, and clotting enzymes; outlines of the chemistry of albumins or proteins; the nitrogen cycle; the sulphur cycle; fermentation of indigo, tea, cocoa, coffee, and tobacco; bacteriological and enzym chemistry in relation to agriculture; and the chemistry of sewage purification.

A bibliography is appended.

Method for determining whether a liquid contains more than one enzym, Achalme and Bresson (Compt. Rend. Acad. Sci. [Paris], 151 (1910), No. 26, pp. 1369–1372; abs. in Analyst, 36 (1911), No. 420, p. 110).—The method rests upon the hypothesis that if a limited quantity of a single enzym be allowed to act simultaneously upon 2 different substrata its action will be distributed between the two. On the other hand, where 2 enzymes are present in a liquid each one of them will act upon a specific substrata and independently of one another.

Microchemical detection of protein, T. Bokorny (Chem. Ztg., 35 (1911), No. 8, pp. 69, 70; abs. in Analyst, 36 (1911), No. 420, pp. 111, 112).—The principle upon which the reaction is based is the coagulation phenomena and the formation of proteosomes observed when the subepidermal cells of some plants belonging to the order Grassulaceae are treated with a solution of caffeine. The proteosome formation is noted in the plasma of the cells in superficial sections of the leaf, which generally exists in the form of closely crowded bodies having an angular or a flat, round shape. The proteosomes may be most conveniently studied with Spirogyra.

The effect of high temperatures on cane sugar in solution, N. Deerr (Hawaiian Sugar Planters’ Sta., Agr. and Chem. Bul. 36, pp. 45).—Continuing previous work (E. S. R., 24. p. 411), “the effect of high temperatures on cane sugar in solution has been studied, and it has been found that at temperatures above 100° C. cane sugar is inverted even in alkaline solutions. The inversion first becomes noticeable at about 110° and increases rapidly with increasing temperature. The connection between rate of inversion at one temperature and at another is given by an expression of the form C1 = C0 e^A(T1 - T0)/T1T0, where C1 and C0 are the rates of inversion at T1 and T0; e is the base of the natural system of logarithm, and A is a constant of value about 25,000.

“Chlorids, bromids, lodds, nitrates, sulphates of the alkalies and alkaline earths, materially increase the rate of inversion at high temperatures in neutral
or in alkaline solutions. The action of the neutral salts of the alkaline earths is much greater than that of the neutral salts of the alkalis. At high temperatures sulphates of the alkalis and alkaline earths, which at lower temperatures retard the rate of inversion, invert cane sugar. Neutral salts of weaker acids act similarly to alkalis and retard inversion at high temperatures. The dominant factor in determining the rate of inversion at temperatures above 100° is the amount of free alkali. The inversion caused by varying quantities of neutral salt is proportional to the amount of salt present. Wilhelmy's law of mass action does not hold as regards quantity of sugar inverted in unit time, but the rate of inversion increases with the time and is about 30 times as great for a 30-minute period as for a 5-minute period.

"The system obtaining in cane juices is a very complex one, consisting of very variable amounts of salts of both strong and weak acids and of free alkali. Hence a temperature which may be safe with one juice may cause serious inversion in another. With the conditions usually prevailing in local factories, juices should suffer a half hour's heating at 120° with no detectable loss of sugar. It would be conservative to adopt this temperature as the highest to which cane juices should be subjected during the process of evaporation, though under a careful system of control and observation a temperature of 125° (or even 130° for shorter periods) might be permissible.

"In the presence of neutral salts of strong acids at high temperatures the isomerization of dextrose is small. It is larger with sulphates of the alkalis and larger still with the alkali salts of weak acids. In the presence of alkalis at high temperatures dextrose is isomerized into a mixture of dextrose and levulose. Simultaneously there is a fall in polarization. The dextrose is in excess of the levulose in proportion about 2:1; a portion of the reducing sugars is destroyed as such, the amount destroyed increasing with increase in alkali.

"When invert sugar is heated [in the presence of neutral salts of strong acids at high temperatures] a portion of the levulose is isomerized to dextrose, the proportion of dextrose to levulose obtaining eventually very similar to what obtains when dextrose alone is heated. As with dextrose, a portion of the reducing sugars disappears and the destruction with invert sugar is comparable to the destruction when dextrose alone is heated. Probably in the presence of alkali a fixed equilibrium between dextrose and levulose obtains, the position of equilibrium being rapidly obtained at high temperatures.

"The sterilization of cane sugar products is possible, since it occurs almost instantaneously at 125°, which is very close to the thermal death point of the most heat resistant sugarhouse bacteria, and since at this temperature in alkaline solution the inversion of cane sugar is very slow.

"The effect of high temperatures on 'clarification' is very small; the most that can be hoped for is a juice from which the dirt might be separated with a little more ease. The dark coloration observed when cane sugar is heated at high temperatures in the presence of alkalis does not indicate a detectable destruction of sugar. The use of high temperature evaporation and the preheater system of evaporation, and also the sterilization of all cane sugarhouse products, is possible under a rational system of control."

Calculation of nonsugars, Demichel (Bul. Assoc. Chim. Sucr. et Distill., 27 (1910), No. 12, pp. 1177–1179; abs. in Amer. Sugar Indus. and Beet Sugar Gaz., 12 (1910), No. 10, p. 368).—"A formula for the approximate calculation of nonsugars in sugar products is given as follows: \( N = 1000 \left( D - D' \right) \frac{G}{G - g} \). In this formula \( N \) represents the nonsugar, \( D \) the density of the impure product, \( D' \) the theoretical density corresponding to the Clerget sugar, \( g \) the specific gravity of water at 15.5° C. (equal to 0.99916) and \( G \) the specific gravity of the
nonsugar which, on the average, is 1.81. By inserting the values of G and g the equation becomes reduced to the more convenient form: \( N = 1.000 \times (D - D') \)

An electrically controlled constant temperature water bath for the immersion refractometer, H. C. Gore (U. S. Dept. Agr., Bur. Chem. Circ. 72, pp. 2, figs. 2).—In this apparatus the inflow of cooling water is regulated automatically by a telegraph sounder pressing upon a rubber outflow tube which controls the admittance of water to the water bath. The thermostat proper consists of a long glass tube filled with mercury, closed at one end and bent into a flat rectangular coil which is fastened to a perforated brass plate resting on feet on the bottom of the water bath. At the open end of the tube is attached a device in which electrical connection is made between the mercury and platinum wires sealed in the tube. The platinum wires connect with the relay and this, in turn, communicates with the sounder mentioned above.

Estimation of formic acid in foods, H. Finscke (Ztschr. Untersuch. Nahr. u. Genussmittel., 21 (1911), No. 1, pp. 1-15; abs. in Analyst, 36 (1911), No. 420, pp. 103, 104). —The Auerbach and Plüddemann method, which utilizes mercuric chlorid for estimating the formic acid, was investigated by the author, who describes procedures for removing the substances, which, when present, interfere with the accuracy of the method. He finds it convenient where numerous estimations are to be made to use the volumetric method, first neutralizing the formic acid solution, then heating it for 2 hours on the boiling water bath with a known quantity of standard mercuric chlorid solution (58.87 gm. of mercuric chlorid and 15 gm. of sodium chlorid per liter), and titrating the excess of mercuric chlorid with potassium iodid solution.

For occasional determinations the gravimetric method may be employed, thereby avoiding the preparation of standard solutions. In this case the formic acid solution is boiled with sodium acetate and an excess of mercuric chlorid under a reflux condenser. The precipitate of mercuric chlorid is weighed after having been successively washed with warm water, alcohol, and ether, and dried at 100° C. For foods it is necessary to acidify the sample with tartaric acid and to distill with steam until a distillate of at least 1,500 cc. has been obtained. Mineral acids are not recommended, as they caramelize the foods and volatile products are given off which reduce the mercuric chlorid.

When acetaldehyde or formaldehyde is present it becomes necessary to interpose a flask containing water and calcium carbonate between the distilling flask and the condenser, the flask being heated during the operation. The formic acid is retained in the flask containing the calcium carbonate, and the calcium carbonate is filtered off and the acid determined in the filtrate.

When sulphurous acid is present the filtrate from the calcium carbonate flask, or the distillate itself, is neutralized and concentrated to a bulk of 100 cc. The solution thus obtained is treated with sodium hydroxid and peroxid, and after standing for 4 hours the excess of peroxid is removed by freshly precipitated mercuric oxid and sodium acetate. After standing for 30 minutes the formic acid is estimated in the filtrate. Salicylic acid yields an insoluble precipitate with mercuric chlorid and sodium acetate, but this precipitation can be prevented by having some sodium chlorid present.

---

constituents are determined is also present in cream. In this work where the total solids, fat, total nitrogen, casein nitrogen, soluble nitrogen, and nitrogen precipitated by tannic acid were determined it was noted that the ratio of fat-free dry substance and nitrogenous bodies to nonfat (plasma) is practically the same in cream and milk.

Investigations in regard to milk serum, A. Burr, F. M. Berberich, and F. Lauterwald (Arb. Vers. Stat. Molkw. Kiel, 1909, No. 6, pp. 26-76).—Of the sera obtained by coagulating milk spontaneously at incubator and room temperatures and with rennet or acetic acid, the acetic-acid serum had the highest specific gravity, while the lowest value was obtained with rennet. Acetic-acid sera also contained the most fat.

It was also concluded that the specific gravity of the serum from fresh mixed milk never falls below 1.026, and that the refraction of spontaneous sera from pure milk never falls below 8 scale divisions of the Woolny refractometer. The spontaneous sera obtained from pasteurized milk were somewhat lower in gravity than those obtained from raw milk, while the specific gravities of sera from buttermilk and cream were found not to be wholly independent of the method of souring the cream and producing the butter.

In judging strongly decomposed milks, the best criterion, according to the authors, is the ash content of the spontaneous serum. They recommend that in addition to determining the fat according to Woolny, when suspicious samples are at hand to note the refraction of the blue solution.

In regard to the phosphorus in the ash of milk, Bordas and Touplain (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 13, pp. 899, 900).—The authors determined the total ash, the ash in the serum (obtained by coagulating the milk with trichloracetic acid), and the ash in the resulting coagulum (casein-butter). The inorganic phosphoric acid, which they believe to be confined to the serum, was determined in the dry substance by calcination, while the organic phosphorus which, according to the authors, is in the coagulum was determined by oxidizing with nitric acid and potassium permanganate according to Marie’s method. A liter of milk was found to contain total phosphoric acid (P₂O₅) 1.063 gm., inorganic phosphorus 1.279 gm., and phosphorus in the coagulum 0.319 gm.

In regard to the titration of milk fluids, F. M. Berberich (Arb. Vers. Stat. Molkw. Kiel, 1909, No. 6, pp. 86-102).—The author sought to verify and investigate the conclusions of others in regard to the irregular results obtained when determining the acidity of milk, etc., in diluted solutions by titration. He found that by adding potassium oxalate to fresh milk a depression in the acidity content took place, and in order to determine which body in the milk was responsible for the depression he tested solutions of phosphoric acid, citric acid, and lactic acid, in combination with calcium salts, magnesium, and potassium, and in the same proportions as they might exist in milk.

No connection between these bodies and the depression could be noted, nor could any relation between the protein substances be determined. According to the author, all irregularities caused by dilution, etc., can be overcome by the addition of 5 cc. of a 30 per cent solution of neutral potassium oxalate to 50 gm. of milk. With it the end reaction with phenolphthalein is also more distinct.

Determination of fat in cream with Woolny’s refractometer, A. Burr and F. M. Berberich (Arb. Vers. Stat. Molkw. Kiel, 1909, No. 6, pp. 84, 85).—Woolny’s refractometer when utilized for cream diluted with water does not yield accurate results. When the cream is diluted with skim milk, however, the refractometer gives figures which correspond more closely to those obtained by the Rose-Gottlieb method.
In regard to the acidity of cream and the buttermilk therefrom, F. M. Derberich and A. Burr (Arch. Vers. Stat. Molk. Kiel, 1909, No. 6, pp. 77–83).—After discussing the various advantages to be derived from determining the acidity during the process of cream ripening, the authors, as a result of making numerous acidity tests, show that a relation exists between the acidity of the ripened cream and that of the resulting buttermilk, the acidity of the latter being the greater. They further note that the acidity in the buttermilk (butter serum) obtained from the butter by kneading it is greater than that in the ordinary buttermilk, the cream, and the water-free cream. They believe that either certain bodies are present in butter which have a great affinity for acid or that the butter fat contributes in some way to the acidity figure. The last supposition seemed the more probable.

A study of the chemical composition of butter fat and its relation to the composition of butter, O. F. Hunziker and G. Spitzer (Reprint from Proc. Ind. Acad. Sci., 1909, pp. 15).—The authors agree with Bell that butter fat consists of a mixture of glycerids in which the glycerol is in combination with three different acids, since the glycerol forms tri- and not mono- compounds. If mono-acid compounds were present, the fat would contain tributyrin, which is soluble in 35 per cent ethyl alcohol. In butter, however, only 1.1 per cent is soluble at 20° C, and 3.3 per cent at 75° C.

The constants found for that portion soluble in cold alcohol (20°) were Reichert-Meissl number 48.1, melting point 16.9°, and soluble acids (as butyric) 9.70 per cent; the portion soluble in hot alcohol (75°) had a Reichert-Meissl number of 29.6, melting point 39.5°, and soluble acids 6.6 per cent. In contrast to these, for the portion not soluble in either hot or cold alcohol, the constants were Reichert-Meissl number 20.7, melting point 38°, and soluble acids 4.26 per cent. The saponification equivalent of the portion soluble in alcohol was 216.5, which is equivalent to a molecular weight of 649.5, and the portion insoluble in alcohol had a saponification equivalent of 290.9 and a molecular weight of 782.7. The molecular weight of butyric is 302. From these results it is evident that tributyrin is not present in butter fat.

From an examination of the hard and soft portions of butter fat fractionated according to Richmond's method, it is concluded that the soft portion contains more volatile or soluble acids and more oleic acid in combination with the glycerol than the hard portion. The melting points of the hard and soft portions were 38 and 13.2°, respectively, as compared with that of 32.5° for the original fat. The difference between the melting point of the insoluble fatty acids of the hard and soft parts was not so great as that of the hard and soft portions of the glycerids from which the acids were derived. The soft portion of the glycerids, however, contained a higher percentage of acid, with a lower melting point. "The iodin number of the soft and hard portions of the insoluble acids is higher than that of the corresponding portions of the glycerids of the butter fat."

In regard to the soluble fatty acids, it was found that in both the hard and soft portions they are in combination with practically the same amount of glycerin. "The percentage of glycerin combined with the insoluble acids is nearly the same in both soft and hard portions, as the percentage of insoluble acids in the soft and hard portions differs very little. Also the variation in the composition of the insoluble acids would not materially affect the molecular weight. Therefore, it is reasonable to expect that nearly the same percentage of glycerin is combined with the insoluble acids of both the soft and the hard portions."

The composition of the butter fat was found to vary with the season of the year and the period of lactation of the animal from which the fat was ob-
tained. "The soluble fatty acids are highest immediately after parturition, or at the beginning of the period of lactation. Slight irregularities excepted, they decreased as the period of lactation advanced and were lowest toward the close of the period of lactation."

Churning tests (12 in number) were conducted in March and May. "In the March butter the percentage increase of the moisture of the soft fats over that of the hard fats was 77.02. In the May butter the percentage increase of the moisture of the soft fats over that of the hard fats was 104.28. These [results] show that the soft fats are capable of taking up a great deal more moisture than the hard fats, [and that] the moisture content of butter made in early summer is due to the increase in the soft fats it contains.

"The moisture-retainning property of the fats is largely dependent on their melting point. The lower the melting point, the greater is their power to mix with and retain water. Since the glycerids of the oleic and soluble fatty acids have a low melting point, it is reasonable [to assume] any increase in the percentage of these glycerids tends to increase the water-retainning properties of butter."

The use of metallic containers for edible fats and oils, J. A. Emery (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 265-282).—This investigation, which was carried on with vessels and sheets of tin plate, galvanized iron, copper, tin, lead, zinc, aluminum, and iron, was for the purpose of determining the action of fats and oils upon metals, with particular reference to the utility of these metals as containers.

The work shows that where an increase in the acid content of the fat or oil was noted there was an increase in the solvent action of the oil for metals, particularly where other favorable conditions, such as heat, moisture, and exposure to the atmosphere, were present. With cotton-seed oil, however, an exception was noted, as this oil, when compared with a corn oil of lesser or approximately the same acidity, showed little or no effect upon metals.

"It [was] demonstrated that zinc, copper, and lead are somewhat readily acted upon, while aluminum, iron, and tin, in the order in which they are named, have offered evidences of higher resisting power and are the metals which would more satisfactorily meet the requirements of both manufacturer and consumer."

Chemistry of fumigation with hydrocyanic-acid gas, C. C. McDonnell (U. S. Dept. Agr., Bur. Ent. Bul. 90, pt. 3, pp. 91-103, fig. 1).—This work considers the chemical problems involved in the liberation of hydrocyanic acid from cyanids, and lays special stress upon the action of mineral acids on cyanids and hydrocyanic acid with particular relation to fumigation.

The residue from the sodium cyanid was found to retain less hydrocyanic acid than the potassium cyanid. A formula recommended as practical for fumigation work is 3 parts sodium cyanid, 4 parts acid, and 6 parts water, the sodium cyanid being expressed in ounces avoirdupois and the acid and water in fluid ounces.

The author points out that all mineral acids cause more or less decomposition of hydrocyanic acid, but that in the amounts in which sulphuric acid is used for fumigation work the loss from this source may be overlooked. As commercial sodium and potassium cyanids contain considerable amounts of sodium chlorid, the author made some tests with mixtures of pure sodium cyanid with from 9 to 66.66 per cent of sodium chlorid. The amount of hydrocyanic acid decomposed varied from 9.62 to 92.09 per cent, and the amount retained in the residue was from 1.4 to 6.63 per cent. One of the principal decomposition products was ammonia, the greater part of which was held in solution in the
generator as ammonium sulphate. Nitrates also were found to exert a decided decomposing action on hydrocyanic acid, but the amount was much less than that produced by chlorids. In view of the important bearing of the sodium chlorid content, an analysis of a cyanid is regarded as of little value in fumigation work unless the chlorid content is also determined.

**METEOROLOGY—WATER.**

Frost data of the United States, and length of the crop-growing season, P. C. Day (U. S. Dept. Agr., *Weather Bur. Bul.* V, pp. 5, charts 5).—Data from observations made in the open country at approximately 1,000 of the cooperative stations of the Weather Bureau having the longest record, usually from about 10 to 30 years, are summarized in a series of charts showing (1) the average date of the last killing frost in spring, (2) the average date of the first killing frost in autumn, (3) the latest date on which a killing frost has occurred in spring, (4) the earliest date on which a killing frost has occurred in autumn, and (5) the average length of the crop-growing season; that is, the number of days between the average date of the last killing frost in spring and the average date of the first killing frost in autumn.

The importance of frost statistics is pointed out and the influence of special conditions on frost formation as indicated by these charts is discussed.

"In the elevated mountain districts and on some of the higher plateaus of the western country freezing temperatures are liable to occur in all months of the summer, but their effect on vegetation is not so pronounced as in the districts east of the mountains.

"Cool nights are a feature of all arid regions, due to the intense radiation made possible by the generally clear skies and the lack of moisture in the atmosphere. As a result of these conditions the temperature in the early morning hours may frequently reach the freezing point but its continuance may not be for a length of time sufficient to injure the plant structure; in fact, owing to the dryness of the air, frost does not always form with a temperature of 32° or even several degrees lower, and in addition plant life subjected to such variations in temperature becomes more hardy and lower temperatures are required to cause serious injury. On the other hand, in the more humid regions the radiation at night is less rapid, the nights as a rule are not so markedly cold, plant life is less hardy, frost forms readily at the freezing point, the same degree of cold is often protracted over much longer periods of time, and vegetation is therefore more seriously affected.

"Throughout the entire mountain and plateau regions there are protected valleys and slopes where the influence of topography on air drainage is sufficient to considerably modify the effect of latitude in the distribution of temperature, and plants and fruits native to localities much farther south may be grown with little fear of injury from frost. There are also localities where on account of the drainage of air from high, snow-covered mountains frosts are more liable to occur than in other localities in the same latitude not so exposed.

"Consideration of these points is essential to the successful locating of sites for orchards and gardens in all hilly and mountainous regions, it being possible to find belts on the sides of mountains or high hills where plant growth begins several weeks earlier in the spring than at the tops of the hills or in the valleys below; and likewise in autumn frosts are delayed to the same extent, thus lengthening the crop-growing season in these belts several weeks.

"The influence of large bodies of water also in tempering the severity of frosts is clearly brought out in these charts, particular attention being invited to the
EXPERIMENT STATION RECORD.

territory surrounding the Great Lakes where at near-by points the length of the frostless season may differ by from 25 to 50 days. Also along the Atlantic coast in southern New England, over Long Island, and in the vicinity of Chesapeake Bay the growing season is as long as in Tennessee, hundreds of miles to the southward.

"Likewise may be seen the increased probability of frost and the consequent shortening of the growing season on the elevated level plateaus, notably in the Berkshire Hills of New England, over the plateau of western New York and north-central Pennsylvania, in the Cumberland Plateau, and in the highlands of Wisconsin and northern Michigan."

Meteorological record (New Hampshire Sta. Bul. 151, pp. 49-72).—Summaries are given of daily observations at Durham, N. H., on temperature, precipitation, direction of the wind, and cloudiness for each month from July, 1908, to June, 1910, inclusive.

Division of meteorology, N. Helme (Rhode Island Sta. Rpt. 1910, pp. 366-383).—Daily observations at Kingston on temperature, precipitation, wind, and cloudiness for each month of the year ended June 30, 1910, are summarized in tables and notes. The mean annual temperature was 48.6°F; the maximum 93°, August 8, 1909; the minimum —7°, January 5 and February 7, 1910. The annual precipitation was 43.71 in., the number of clear days 158, and the prevailing direction of the wind west. The year was characterized by very dry weather in July and August, 1909. The last frost was observed June 5, 1910.

Meteorology, practical and applied, J. W. Moore (London, 1910, 2, rev. and ed., pp. 492; rev. in Lancet [London], 1910, II, No. 26, pp. 1837, 1838).—This is a second revised and enlarged edition of this well-known treatise, which in its new form is thoroughly up-to-date.

The South's rainfall and temperature in relation to southern agricultural monopolies, W. A. Withers (Tradesman, 65 (1911), No. 11, pp. 44, 45).—The relation of rainfall and temperature to the production of cotton, tobacco, rice, sweet potatoes, sugar cane, and peanuts in the South is discussed. It is shown that conditions of rainfall and temperature are especially favorable to the production of these crops in different parts of the South.

The climate of Hungary, S. Róna (Met. Ztschr., 28 (1911), Nos. 1, pp. 16-28; 2, pp. 53-66).—This is a summary of a large work in two volumes on this subject published in the Hungarian language.

Underground water papers, 1910 (U. S. Geol. Survey, Water-Supply Paper No. 258, pp. 123, pls, 2, figs. 32).—This paper contains a series of short articles reporting the results of special or subordinate investigations as follows:

Drainage by wells, M. L. Fuller (pp. 6-22).—The emptying of sewage and industrial wastes into drainage wells is condemned, but the drainage of most ponds and swamps into wells is considered unobjectionable.

The freezing of wells and related phenomena, M. L. Fuller (pp. 23-31).—It is shown that the freezing of wells is due to access of air to the pipe at considerable depths and not to transmission of cold outside air through the casing, and that methods of protection which do not recognize this fact fail.

Occurrence and composition of well waters in the states of Maine, F. G. Clapp (pp. 32-39).—Investigations reported show that plenty of excellent water can be found in most of the metamorphic slates of Maine, generally at depths of from 200 to 300 ft. The deeper wells are safer from pollution.
Occurrence and composition of well waters in the granites of New England, F. G. Clapp (pp. 40–47).—Most of the wells drilled in granite in New England yield enough water of good quality for the domestic needs of a family.

Pollution of underground waters in limestone, G. C. Matson (pp. 48–56).—The putting of sewage or filth of any kind in limestone sinks is condemned as likely to pollute underground water channels for long distances from the source of contamination.

Protection of shallow wells in sandy deposits, M. L. Fuller (pp. 57–65).—It is shown that pure water is sometimes obtained from shallow wells in polluted sands. This is explained as due to the fact that “the alternation of layers of materials of different texture, even if all are pervious, and the presence of stratification planes in uniform materials tend to obstruct the downward passage of water and to confine pollution to the upper portion of the ground-water body—the part immediately below the water table.”

Saline artesian waters of the Atlantic coastal plain, S. Sanford (pp. 75–86).—Areas, usually in low ground and near large bodies of salt water, where salt water may be obtained, are more numerous than has been supposed. “There is no foundation for the opinion that fresh water can always be found below salt or can be found in a particular formation where salt water has been found in an overlying formation.”

There are also papers on Composition of Mineral Springs in Maine (pp. 66–74), and Underground Waters near Manassas, Va. (pp. 94–97), by F. G. Clapp; Magnetic Well, by M. L. Fuller (pp. 87–93); and Utilization of the Underflow near St. Francis, Kans., by H. C. Wolff (pp. 98–119).

The quantities of chlorin and sulphur carried into the soil by atmospheric precipitation, I. A. Vityn (Zhur. Op'ychn. Agron. (Russ. Jour. Exp. Landw.), 12 (1911), No. 1, pp. 29–32).—From results of analyses of atmospheric precipitation collected at 8 different places in Russia and of drainage waters from lysimeters filled with sandy soil the following conclusions are drawn:

The atmospheric precipitation carried considerably more chlorin and sulphur into the soil than was contained in relatively high yields of grain and straw. The principal source of chlorin was sea water, from which it was carried in the form of sodium chlorid. The principal source of sulphuric acid was sulphurous acid, a product formed from burning wood and coal, as was borne out by the fact that soils of regions where forest industries and coal mines were most numerous showed the highest sulphuric acid content.

For the St. Petersburg district the highest quantities of chlorin were precipitated in the spring and fall, this being associated with the prevailing west sea winds. The sulphuric acid content was highest for the St. Petersburg and Mariupol districts in winter, the time when much wood and coal was burned in the homes, and when the factories increased their activity.

Increased precipitation for brief periods of time decreased the chlorin and sulphuric acid contents of the precipitation. The lysimeter water for a given length of time contained somewhat higher quantities of chlorin and sulphuric acid than were precipitated.

Home waterworks—a manual of water supply in country homes, C. J. Lynde (New York, 1911, pp. XII + 270, figs. 106).—In this handbook, which the author considers suitable for reading and study by children in continuation classes and in high schools, the general questions of water supply are considered and also problems of bringing water into the house, methods of pumping, plumbing and sewage disposal, water power, and related matters.

Organic phosphoric acid of the soil. G. S. Fraps (Texas Sta. Bul. 136, pp. 33).—The author determined the amount of phosphorus soluble in 4 per cent ammonia, and fifth and 1.8-normal nitric acid, in a number of Texas soils before and after ignition. The extraction was made with ammonia directly and after previous extraction with 1 per cent hydrochloric acid, as in the official method. Stewart's ignition method (E. S. R., 23, p. 423) was used, which is in brief as follows:

"A portion of the soil is ignited, extracted with cold 12 per cent hydrochloric acid, and the phosphoric acid estimated. From this is subtracted the amount of phosphoric acid extracted from the original soil by the same process, and the result is taken to represent the organic phosphorus. The method is based upon the tacit assumption that the effect of the ignition is to destroy the organic phosphorus compounds and so render the phosphorus soluble in acids, without affecting the solubility of the inorganic phosphates."

The conclusions drawn from this work are as follows:

"Phosphoric acid is present in the soil as organic phosphates, as phosphates of lime, and as phosphates of iron and alumina.

"The ammonia-soluble phosphoric acid is partly inorganic and partly organic.

"Ammonia dissolves phosphoric acid chiefly from phosphates of iron and alumina.

"Some soils may fix phosphoric acid from ammonia solution.

"The concentration of the phosphoric acid in ammonia or fifth-normal nitric acid increased with the quantity of soil present, but the parts per million of phosphoric acid extracted from the soil decreased as the quantity of soil was increased. This behavior of the soil phosphates toward ammonia is not in accord with the theory that the ammonia merely combines with organic compounds containing phosphorus.

"The quantities of iron and alumina, lime and magnesia dissolved by the ammonia were small.

"Phosphoric acid fixed by the soil was partly extracted by acid, partly extracted by ammonia, and a portion remained in the soil.

"Organic matter added to the soil increases the ammonia-soluble phosphoric acid. As the organic matter decays, the ammonia-soluble phosphoric acid usually decreases, though sometimes it increases.

"An increase in ammonia-soluble phosphoric acid during decay does not necessarily mean an increase in organic phosphoric acid.

"Phosphoric acid is dissolved by ammonia from ignited soils. This is evidence that the ammonia-soluble phosphoric acid is partly of inorganic origin.

"More phosphoric acid was dissolved from ignited soils by ammonia, after extraction with acid, than from the same soils before extraction. The increase in ammonia-soluble phosphoric acid brought about by the action of acid on the soil is thus not necessarily entirely due to the liberation of organic compounds containing phosphoric acid, which are dissolved by ammonia.

"Ammonia has a greater solvent action upon some mineral phosphates (wavel- lite) than has 1 per cent hydrochloric acid.

"Twelve per cent hydrochloric acid does not extract all the phosphoric acid of wavellite, variscite, or dufrenite.

"Ammonia extracts more phosphoric acid from wavellite than does 12 per cent hydrochloric acid.

"An extraction with ammonia following an extraction of the soil with 12 per cent hydrochloric acid may dissolve more inorganic phosphoric acid than a second extraction with 12 per cent acid."
"Ignition has a marked effect on the solubility of phosphates in acids. Wavellite, dufrenite, and variscite become almost completely soluble.

"About ten times as much phosphoric acid was dissolved by fifth-normal nitric acid from the ignited minerals tested, as from the nonignited.

"Ignition increases the solubility in 12 per cent hydrochloric acid of the iron oxid and alumina in the soil, sometimes to a very great extent.

"Increase in the phosphoric acid dissolved by hydrochloric acid caused by ignition is no evidence that such phosphoric acid is in organic combination.

"The method of ignition and solution can not be used as a method for estimating the organic-phosphoric acid of the soil.

"From 12 to 100 per cent of the ammonia-soluble phosphoric acid of the soil (average 51 per cent) was present in the ignited soils.

"There was no definite relation between ammonia-soluble and ignition-soluble phosphoric acid in the soils tested.

"The ignition-soluble and the ammonia-soluble phosphoric acid do not represent the same thing.

"A high content of ignition-soluble phosphoric acid was associated with a relatively high content of nitrogen and of oxids of iron and alumina in the soils examined. A high content of nitrogen was not, however, always accompanied with a high content of ignition-soluble phosphoric acid.

"When the soils were grouped according to their content of ignition-soluble phosphoric acid, the average nitrogen content increased with the average ignition-soluble phosphoric acid, though not regularly. The average content of iron oxid and alumina also increased.

"We have at present no method for estimating the organic phosphoric acid of the soil."

Character and leaching of podzol soils, G. Tumin (Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 12 (1911), No. 1, pp. 1-19).—It is stated that the character of the podzol soil does not depend upon leaching. Three types of podzol soils are distinguished. The real podzol consists of a gray surface layer, underlain with a white sole, beneath which occurs a white mottled grayish brown soil. In a less characteristic podzol the white layer tends to merge into the gray surface soil, and in a slightly characteristic podzol there is no white layer. These variations in the color of the soil, as well as the leaching properties, are dependent upon the humus content, the white layer of soil marking the depth to which decomposition of the organic matter takes place.

On the relation of clay soils to water, the limits and degrees of their plasticity, A. Atterberg (K. Landthr. Akad. Handl. och Tidskr., 50 (1911), No. 2, pp. 132-158, figs. 3).—The author gives a classification of clay soils and reviews the various methods for the determination of their degree of plasticity. The methods of examination worked out by him are given in detail in the paper. See also a previous note (E. S. R., 25, p. 116).

The soil, a living thing, J. W. Harshberger (Science, n. ser., 33 (1911), No. 854, pp. 741-744).—In this article the author, like Berthelot, conceives of the soil as a living thing apart from its chemical and physical structure and suggests "that in the reaction between the living soil and the growing plant is the true explanation of soil fertility. A fertile soil is a live one. An infertile soil is a dead one. Contrast the soil which is filled with organic matter (humus) and in which numberless fungus, bacterial, and protozoan organisms are at work with a mass of clay or sand without such organic material and associated living organisms. The one soil is fertile, because the organisms in the soil react favorably upon each other, the other soil is infertile, because the organisms present in this soil are antagonistic."
Recent investigations bearing upon the interrelation and interdependence of plants and soil organisms are reviewed as indicating “the way along which future research on soils must proceed.”

Enzymatic activities in soils, O. Schreiner and M. X. Sullivan (Abs. in Science, n. scr., 33 (1911), No. 844, p. 339).—The author points out that amylolytic, proteolytic, cytolytic, lipolytic, and inverting enzymes exist in the soil. “The oxidizing and catalytic activities of the soil, comparable to the same activities in plants and animals where it has been attributed to enzymes, are especially noticeable and easy of demonstration. As yet no satisfactory means have been obtained of extracting enzymes from soil to any great extent, though in soils recently cropped there is some slight evidence of the presence of enzyme-like substances in the glycerin extract of the soil.”

Two compounds isolated from peat soils, C. S. Robinson (Jour. Amer. Chem. Soc., 33 (1911), No. 4, pp. 567-568).—The author isolated lentin and isoleucin from a sample of common brown peat. A sample of black peat was also examined, but the material obtained was too small to permit a separation of the isomers.

The isolation of creatin in from soils, E. C. Shorey (Abs. in Science, n. scr., 33 (1911), No. 844, p. 340).—Creatin was isolated from various soils. The method used is described in detail.

Productivity of soils, F. H. King (Science, n. scr., 33 (1911), No. 851, pp. 613-619).—This is a review of a paper by Chamberlin on the secular maintenance of soils (E. S. K., 24, p. 769), in which exception is taken to certain of the conclusions drawn in that paper, particularly those relating to the maintenance of the supply of potash and phosphoric acid in the surface soil as a result of the so-called capillary and plant cycles.

Examination of soil samples (U. S. Dept. Agr., Bur. Soils Circ. 26, pp. 7).—This circular outlines the procedure of the Bureau of Soils in examinations of soil samples submitted by correspondents, discusses different factors which must be taken into consideration in judging of the character and adaptation of soils, and specifies the information that should accompany soil samples sent to the Bureau for examination.

Soils of the Eastern United States and their use.—III, The Portsmouth sandy loam, J. A. Bonsteel (U. S. Dept. Agr., Bur. Soils Circ. 24, pp. 12).—This, the third of this series of circulars, deals with the Portsmouth sandy loam, of which a total area of 774,052 acres in 21 different areas in 9 States has been surveyed by the Bureau of Soils.

Soils of the Eastern United States and their use.—IV, The Sassafras silt loam, J. A. Bonsteel (U. S. Dept. Agr., Bur. Soils Circ. 25, pp. 14).—This, the fourth of this series of circulars, deals with the Sassafras silt loam, of which a total area of 518,142 acres in four different States has been surveyed by the Bureau of Soils.

[Soils of the Hawaiian Islands], E. V. Wilcox (Hawaii Sta. Rpt. 1910, pp. 11, 12).—The soils of the Hawaiian Islands are very different in several respects from those which are familiar to farmers and agricultural workers on the mainland. In the first place, the Hawaiian soils contain high percentages of iron in various forms (say from 15 to 30 per cent). In addition to the high iron content, the soils contain more titanium than mainland soils, and in some localities also a large amount (up to 9 per cent) of manganese. The presence of the large quantity of iron in Hawaiian soils gives them physical properties which are seldom met with in soils on the mainland. Wherever special attention is not given to cultivation, the soils rapidly become impervious to water and air, and the iron present in the soil is reduced to the ferrous state. This, as is well known, is injurious to plant growth and is instrumental in prevent-
ing adequate aeration of the soil. Moreover, when the iron exists in the ferrous state, and the soil can not be aerated, the use of fertilizers gives little or no benefit. It is therefore necessary to adopt a rational soil program with the central idea, that of securing a better aeration and better physical properties of the soil. Studies, which are designed to throw light on the practical methods of accomplishing such a result, are now in progress at the station, and the suggestions, already made by the station chemist, are being put into practice in a number of localities. It may be truthfully said that in many localities the chief soil problems are concerned with the physical rather than the chemical properties of the soil. Improper aeration not only causes the iron to become reduced to the ferrous state, but may also prevent the utilization by the plant of the plant food naturally present in the soils."

The Hawaii Station is studying, by means of pot and field experiments, cultural and rotation methods for securing better aeration of the soil.

Deli soils, J. G. C. Vriens and S. Tilmstra (Medcd. Deli-Proefstat. Medan, 5 (1911), Nos. 6, pp. 145-167; 8, pp. 250-295, map 1).—In this article, which reports a continuation of investigations (E. S. R., 24, p. 713), results of studies on the relation of various physical soil factors to each other and to the chemical constituents of the soil are reported. Among the more important conclusions reached are the following:

The nitrogen-fixing power and the water-holding capacity varied with the fineness of the soil, being highest from the finest soils. A high nitrogen-fixing power was associated with a high water capacity, a low absorptive capacity, and a low porosity, whereas a low nitrogen-fixing power indicated a low water capacity. A high nitrogen content was associated with a high water capacity and a low absorptive capacity, whereas a low nitrogen content indicated a low water capacity and high porosity. A medium to high phosphoric acid content was associated with a high water capacity and a low volume weight; a good phosphoric acid content went with a high absorptive capacity and a high porosity. A high potash content went with a low retentive power with a decrease in volume, whereas a low potash content indicated a high water capacity, a medium retentive power with increase in volume, a low volume weight, high absorptive capacity, and high porosity. A high lime content went with a high nitrogen-fixing power and a high water capacity. No definite relation between lime content and absorptive capacity, volume weight, and porosity could be established.

Deli soils, J. G. C. Vriens (Medcd. Deli-Proefstat. Medan, 4 (1910), No. 6, pp. 177-180; 5 (1911), No. 8, pp. 255-257).—This is a continuation of the report on the analyses of tobacco soils previously noted (E. S. R., 23, p. 224).

Methods and results of ten years’ soil investigations in Illinois, C. G. Hopkins (Illinois Sta. Circ. 149, pp. 12-32, figs. 5).—This is an address delivered before the Illinois State Farmers’ Institute in February, 1911, and gives an account of the plan, purpose, and progress in three lines of soil investigation carried on by the Illinois Experiment Station, (1) soil surveys, (2) soil analyses, and (3) culture experiments.

A list of firms from which natural rock phosphate, bone meal, potash salts, and ground limestone may be obtained is added.

Results of scientific soil treatment, F. I. Mann (Illinois Sta. Circ. 149, pp. 3-11, figs. 5).—This is an address delivered before the Illinois State Farmers’ Institute in February, 1911, and deals with the method of soil improvement, namely, use of raw phosphate in a rotation of cereals and leguminous plants, recommended by the Illinois Experiment Station.

The natural plant food content and fertilizer requirements of soils, F. Leden (Gartenflora, 60 (1911), Nos. 2, pp. 25, 26; 5, pp. 94-106).—This is a
brief popular summary of the more recent investigations on this subject with special reference to horticultural crops.

Debated fertilizer questions, Schiedewind (Ztschr. Angew. Chem., 23 (1910), No. 12, pp. 567, 568).—The questions briefly discussed in this article are soil robery, sodium nitrate versus ammonium sulphate as a fertilizer, the most efficient forms of phosphoric acid and potash, and the lime-magnesia ratio in soils.

The purchase and home mixing of fertilizers, F. W. Taylor (New Hampshire Sta. Circ. 12, pp. 2-12).—This circular explains how to interpret a fertilizer guarantee and the advantages of high-grade as compared with low-grade fertilizers and of home mixing of fertilizers, and gives directions for home mixing with formulas for different crops.

On the value of peat litter, J. J. Tyrväi (Hedecelsk. Tidsskr., 1911, No. 7, pp. 71-83).—A description is given of the method of manufacture and of Danish experiments with peat litter as an absorbent for liquid manure. It is shown that losses of nitrogen in liquid manure can be entirely avoided by the use of sufficient quantities of peat litter as an absorbent.

A new ammonia salt (Saaten, Dünger u. Futtermarkt, 1911, No. 8, pp. 219, 220; abs. in Jour. Agr. Prat., n. serv., 21 (1911), No. 10, pp. 300, 301; Betterw., 21 (1911), No. 527, pp. 103, 104).—This article briefly describes a cheap process for preparing a by-product of gas manufacture consisting mainly of ammonium sulphite and sulphate. Experiences are cited in which good results were obtained with this material in comparison with ammonium sulphate in fertilizer experiments on wheat, rye, oats, barley, potatoes, beets, and grass.

Nitrate industry of Chile, H. P. Fletcher (Daily Cons. and Trade Rpts. U. S.), 11 (1911), No. 94, pp. 319, 314).—Statistics furnished by the Nitrate Propaganda are quoted, showing a production of 2,667,000 tons during 1910 as compared with 2,275,559 tons in 1909. The estimated production for 1911 is 2,794,000 tons.

The importance of phonolite as a potash fertilizer, T. Pfeiffer, E. Blanck, and M. Flügel (Mitt. Landw. Inst. Breslau, 6 (1911), No. 2, pp. 233-272; abs. in Deutsch. Landw. Presse, 38 (1911), No. 8, pp. 79, 80; Ztschr. Angew. Chem., 24 (1911), No. 17, pp. 804, 805).—This article reviews other investigations on the fertilizing value of potassium silicate and reports pot and field experiments, comparing phonolite with potash salts on various crops. Incidentally tests were also made of humus-silicic acid. The results agree in showing a certain fertilizing value for this material, although it was much less effective than the potash salts. No beneficial effect resulted from the use of the humus-silicic acid.

Various experiments with raw phosphates, D. N. Prianishnikov et al. (Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 17 (1911), No. 1, pp. 1-141, figs. 16).—This article reports trials of various methods of preparing superphosphates from different kinds of Russian phosphates as well as tests of the raw phosphates on different crops in sand cultures.

Experiments with bone meal, D. N. Prianishnikov et al. (Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou), 17 (1911), No. 1, pp. 142-176, figs. 8).—The experiments here reported indicate that bone meal is more sensitive to the conditions under which it is used than superphosphate or Thomas slag. The efficiency of the material as a fertilizer was reduced by the addition of calcium carbonate, and increased by the addition of ammonium salts and by the substitution of nitrogen obtained from the air through leguminous plants for nitrate nitrogen. When nitrate nitrogen was used better results were obtained by applying it separately than with the bone meal. The bone meal gave better results in larger pots more abundantly supplied with
moisture than in smaller pots. Better results were obtained by watering from above rather than from below and by late rather than early seeding.

On the sale of Martin slag containing fluorin for Thomas slag, O. Lemmermann (Illus. Landw. Ztg., 30 (1910), No. 91, p. 857).—It is stated that Martin slag containing 6.31 per cent of phosphoric acid, of which 1.38 per cent was soluble in citric acid solution, and an appreciable amount of fluorin, was found to be on sale as a substitute for Thomas slag.

A few notes on lime for agricultural purposes, B. E. Curry (New Hampshire Sta. Circ. 13, pp. 4).—This circular describes different forms of lime and discusses their relative value for fertilizing purposes, especially under New Hampshire conditions.

The valuation of lime marl, Gerlach (Deut. Landw. Presse, 38 (1911), No. 35, p. 409).—Results of pot experiments confirmed the conclusions of Baessler that the solubility of calcium carbonate in lime marls depends upon the percentage of calcium carbonate and the degree of fineness of the crude product. For practical purposes it is recommended that the marl be of such fineness as to allow 99 per cent of it to pass through a $\frac{1}{2}$ mm. sieve.

Fertilizer inspection (Maine Sta. Off. Insp. 29, pp. 36).—This reports the results of analyses of fertilizers inspected in Maine during 1910, with explanations regarding the analysis and valuation of fertilizers and comments upon the results of inspection.

Analyses of fertilizers, spring season, 1911, B. W. Kellogg et al. (Bul. N. C. Dept. Agr., 32 (1911), Nos. 3, pp. 83; 4, pp. 93).—Analyzes and valuations of fertilizers collected in North Carolina during the spring of 1911 are given, with a list of manufacturers and brands licensed for sale in the State for the season of 1910-11, explanations of terms, and freight rates from the seacoast to inland points.

Analyses of licensed commercial fertilizers, 1911, F. W. Wolf (Wisconsin Sta. Circ. Inform. 25, pp. 12).—This circular gives a list of commercial fertilizers licensed for sale in the State during the year, with guarantees of composition and results of analyses of samples furnished by the manufacturers and collected by agents of the station. Brief explanations are also given of the terms used in stating analyses and valuation of fertilizers.

List of fertilizer manufacturers and importers (Penn. Dept. Agr. Bul. 205, pp. 37).—This list gives not only names and addresses of the manufacturers and importers, but names of the "brands of their fertilizers for which license to sell in Pennsylvania during 1911 was taken out prior to February 21, 1911."

AGRICULTURAL BOTANY.

Protective enzymes, M. T. Cook et al. (Science, n. ser., 33 (1911), No. 851, pp. 624-629).—This is a preliminary report of studies made by the authors which show the important relations and reactions carried out by certain protective enzymes of fruits. The work originated in experiments begun to determine the toxicity of tannin. Most of the experiments were carried on with pomaceous fruits, although those of the tomato and other plants were used.

The authors, summarizing their investigations, state "that there exists in the normal living fruit two enzymes, a catalase and an oxidase. The latter is probably most abundant in the early part of the season, gradually decreasing in activity as the fruit approaches maturity and ripens. Furthermore, from the above results it appears that tannin as such does not exist in any part of the normal, uninjured fruit previous to maturity, except possibly a small amount in the peel, but exists as a poly-atomic phenol, which upon injury is acted upon

4496°—No. 4—11——3
by the oxidase and forms a tannin or tannin-like body having the property of precipitating protein matter, and at the same time forming a germicidal fluid. This oxidase acts only in an acid solution, and when present in an amount above a certain undetermined minimum. The above conditions are always present in normal immature pomaceous fruits. When normal, immature fruits are subjected to injury by fungi, insects, or mechanical agencies, the action of the oxidase on poly-atomic phenol is brought about with the effects as stated above."

Some properties characteristic of amylase and amyllopectin, Mme. Z. Gruzewska (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 12, pp. 785-788).—A study has been made of potato starch, and by means of a method described the author states that the starch grain can be easily separated into two distinct bodies, amylase and amyllopectin. Amylopectin and mineral matter compose the envelope of the starch grain, while amylase is localized in the interior. Amylase, like inulin and some other bodies, has the property, upon becoming old, or under the action of cold, of precipitating from its solutions. This phenomenon has been called retrogradation. Purified amyllopectin is not precipitated from its solutions either upon standing or under the influence of cold.

On the formation of anthocyanin, Mss. M. Whedale (Jour. Genet., 1 (1911), No. 2, pp. 133-158).—The author has made a study of anthocyanin to determine the chemical processes which underlie its formation.

On summarizing her results it is said that the soluble pigments of flowering plants, collectively termed anthocyanin, are oxidation products of colorless chromogens of an aromatic nature which are present in the living tissues in combination with sugar as glucosids. The formation of the glucosid from chromogen and sugar is in the nature of a reversible enzym action. The chromogen can be oxidized to anthocyanin only after liberation from the glucosid, and the process of oxidation is carried out by one or more oxidizing enzymes. The amount of free chromogen, and hence the quantity of pigment formed at any time, is inversely proportional to the concentration of sugar and directly proportional to the concentration of glucosid in the tissue. The local formation of anthocyanin which is characteristic of the normal plant is due to local variation in concentration of either the free sugars or the glucosids in the tissues in which the pigment appears. The abnormal formation of pigment is attributed to differences in the concentration of these same substances due to changes in metabolism.

The application of the hypothesis relating to anthocyanin to Mendelian factors is discussed.

The absorption of colloidal organic material, P. Mazé (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 12, pp. 783-785).—Studies were made with maize grown in cultures to which starch, peptone, and humus compounds were added in connection with salts of ammonia. The absorption of the colloidal organic matter, as well as its assimilation, was demonstrated. Under the influence of the products of excretion a neutral solution containing humus was acidified, while in another series the solution remained neutral on account of the liberation of soda.

The starch did not present any trace of liquefaction or saccharification, nor did it show the presence of amylase. Preliminary investigations indicated that sucrase in the solutions gave negative results. The roots did not excrete either amylase or sucrase, contrary to common belief. The saccharification of starch and the inversion of saccharose was brought about at length under the influence of the progressive acidification of the nutrient solutions.

The action of some hydrolyzable salts and colloids on plants, A. Grégoire (Bull. Soc. Chim. Belg., 25 (1911), No. 2, pp. 85-103).—In a previous publication (E. S. R., 23, p. 527), the author showed that certain readily hydrolyzable salts
had an important effect on the growth of rye. In 1910 he continued his experiments, using barley as a representative of cereals, the ash of which is said to be acid in reaction, and sugar beets, the ash of which is alkaline. The plants were grown in water cultures containing a nutrient solution, to certain series of which were added a number of compounds, as silica, aluminum hydrate, straw gum, calcium lanate, palmitate, humate, carbonate, and zeolite, and sodium zeolite. After about 4 months the plants were analyzed and their ash, dry matter, etc., determined.

As a result of this investigation the previous conclusion is confirmed that certain hydrolyzable salts which do not act as plant nutrients still have a very important rôle in connection with plant growth. Barley and probably all of the Gramineae do not develop normally except in solutions containing colloidal silicic acid, and they were found to be extremely sensitive to certain organic compounds, especially humic acid. On the contrary, the sugar beet flourishes in the presence of humic acid in the nutrient solution, but suffers considerably in the presence of silicic acid.

In making some deductions from his experiments the author states that the favorable action of ammonium sulphate as compared with nitrate of soda on the Gramineae may be explained by the fact that the ammonia is physiologically acid and its introduction into the soil probably results in a mobilization of the silicic acid. He also states that manure applied to spring grains has a detrimental effect, due to the formation of calcium humate, which is injurious to grasses.

Combined influence of zinc and manganese on the development of Aspergillus niger, G. Bertrand and M. Javillier (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 13, pp. 900-902).—In a previous publication attention is called to the catalytic action of certain substances and their effect on plant growth (E. S. R., 21, p. 723). In a subsequent paper a report is given on the effect of manganese on the development of A. niger (E. S. R., 25, p. 127), and in the present article an account is given of the combined action of zinc and manganese used in considerable dilution upon the growth of this fungus.

It was found that when added to cultures containing the fungus the combined influence of zinc and manganese was of decided advantage, not only when used in proportions which previous experiments had shown were the optima for the different compounds used singly, but also when used in less quantity.

The authors claim that the catalytic action which various substances have toward plant cells is of especial economic importance.

The retention of mineral matter by annual plants, and the distribution of the dry matter, total ash, and nitrogen, G. André (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 12, pp. 777-780).—In a previous paper (E. S. R., 24, p. 721), the author reported the retention of practically all the mineral matter taken up through the roots of annual plants. In the present article the results are given of studies on the distribution of dry matter, ash, and nitrogen in the roots, stems, leaves, and fruits of carnations at various stages of growth.

The dry matter of all parts of the plants constantly increased up to maturity. The total weight of ash increased in all the plant organs except in the leaves, where there was a loss of about 5 per cent between the beginning of maturity and its final completion. The total nitrogen increased in the roots until after flowering, when it decreased slightly, gaining again at maturity. In the leaves the total nitrogen attained its maximum at the period of flowering. In the stems and fruits it increased with practically every succeeding stage of growth. The percentage of nitrogen in comparison with the dry weight diminished constantly through the different periods, although the loss was very slight in the fruits.
The phenomena of phosphoric acid migration are more regular than those described for nitrogen, while potash is said to behave essentially as does nitrogen.

The selective power of plants for dextrose and levulose, L. Lindet (Bul. Assoc. Chim. Sucr. et Distill., 28 (1911), No. 10, pp. 727-743; abs. in Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 12, pp. 775-777).—The author found in previous experiments (E. S. R., 12, p. 113) that beet leaves when constantly in contact with dextrose and levulose absorbed dextrose when respiration was active and levulose when growth was rapid. He has recently extended his experiments to include yeasts, aerobic fungi, and embryos of beans and barley.

With the yeast, dextrose was found to induce a much greater zymotic action than did levulose. With the barley and bean embryos, dextrose was taken up from the solution in the proportion of 1.7 to 1 of levulose. For the same amount of each sugar taken up the weight of the plantlets was twice as great for the levulose as for the dextrose. With the fungi, reproduction was increased by levulose, and respiration by dextrose.

All the experiments show, it is claimed, that the absorption of levulose from cultures is attended with the functions of growth, while dextrose is associated with the respiration.

The action of ultraviolet rays on starch, L. Massol (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 13, pp. 902-904).—According to the author, the exposure of soluble starch, prepared by heating it for a considerable time, to the light of a mercury-quartz lamp so changes the starch that it loses after a while its property of becoming blue when acted upon by iodin. The rapidity of the transformation increases as the concentration decreases and when the medium has become acidified. This transformation, which is interesting from the point of physiological botany, the author claims is due to the photochemic action of the light and not to the influence of the acid, the temperature, or oxygenated water.

Recent investigations on the alleged utilization of atmospheric nitrogen by certain special hairs of plants, F. Kövessi (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 13, pp. 888-890).—In continuation of a previous communication (E. S. R., 22, p. 230), the author reviews experiments to verify the theory announced by Juleson (E. S. R., 18, p. 125) and Zemplén and Roth (E. S. R., 22, p. 521) relating to the acquisition of atmospheric nitrogen by plants through special trichomes. He has made a study of a considerable number of plants, growing them in air and in an atmosphere deprived of nitrogen, and has found nothing to change his previous opinion. On the contrary, it was found that in the two lots of plants the hairs described were developed equally and produced the same reactions when tested with the reagents recommended.

On the “air culture” of green plants, V. Artsikhovskii (Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 11 (1911), No. 1, pp. 46-53, figs. 6).—As the root tubercles of leguminous plants develop either very poorly or not at all in water cultures, the author has devised a method of growing the plants in air cultures.

The roots were allowed to develop in a moist chamber composed of an inverted flowerpot with its top plunged into water contained in a plate, and the roots, which were above the water, were sprayed several times a day with a nutrient solution. By such a device the author claims to have successfully grown Pisum sativum with an abundant development of root tubercles.

The nuclear conditions in certain short-cycled rusts, E. W. Olive (Science, n. ser., 33 (1911), No. 840, p. 194).—The author recognizes 2 general types of
the short-cycled lepto rusts and micro rusts with reference to the time of inauguration of the binucleate condition. In one type, illustrated by *Puccinia exigua*, *P. asteris*, and *P. malvacearum*, the binucleate condition arises at the base of the young telutospore sori. In the other type the binucleate condition arises at some indefinite point earlier in the life history in the vegetative mycelium. *Uromyces rudbeckiae* was found to present an enigmatical variation in which all cells, telutospores as well as vegetative mycelium, possessed each but one nucleus.

The theory and practice of plant breeding, H. LANG (Theorie und Praxis der Pflanzenzüchtung. Stuttgart, 1916, pp. VIII+169, figs. 47).—This textbook gives practical directions for plant breeding experiments, and describes various aids that have been found of advantage in the manipulations attending plant breeding, selection, and fixation of new forms, after which a discussion is given of heredity, natural selection, correlation, etc. Special chapters are devoted to the problems of breeding wheat, rye, barley, oats, beets, potatoes, maize, red clover, and tobacco.

A rather extensive bibliography of plant breeding is given.

Alterations in heredity induced by ovarial treatments, D. T. MACDOUGAL (Bot. Gaz., 51 (1911), No. 4, pp. 241-257, pls. 3, figs. 3).—For a number of years the author has carried on experiments to determine the effect of injecting various solutions into the ovaries of different plants, a preliminary account of which has been given (E. S. R., 19, p. 1127). The present paper gives an account of the progress that has been made, and includes a description of the technique and character of the plants employed, together with the results of the culture of the affected species through a number of generations.

The earlier conclusions that the sum of hereditary characters in pedigreed lines of plants may be altered by solutions applied to the ovaries in the stage immediately preceding fertilization have been confirmed, and some of the derivatives have been carried through several generations.

Experimental studies in Indian cottons, H. M. LEAKE (Proc. Roy. Soc. [London], Ser. B, 83 (1911), No. B 566, pp. 447-451).—The author made a study of the types of cotton most cultivated in India, particularly of those types common to northern India. He states that they fall into two groups, which are characterized by the form of the secondary branches, which may be either monopodial or sympodial. The experiments reported cover observations on color of corolla, red coloring matter of sap, leaf factor, type of branching and length of vegetative period, and glands of the leaf.

From an economic standpoint the author states that it is essential that plants of the sympodial type should be cultivated in the United Provinces of India to be a commercial success, for the monopodial types do not flower in time to give a crop before the winter sets in. The majority of Indian cottons with a valuable staple, it is said, belong to the monopodial type, and the problem for the plant breeder is the isolation of sympodial forms with the staple of the monopodial type.

Studies on the variability and heritability of pigmentation in *C*enothera, R. R. GATES (Ztschr. Induktive Abstand. u. Vererbungslehre, 4 (1911), No. 5, pp. 337-372, pl. 1, figs. 5).—A summary is given of observations made during the past 4 years on the variation and inheritance of the red pigment, anthocyanin, in *C*enothera. The studies concerned the development of the red color pattern, which occurs particularly on the calyx in many forms, but which may also appear in other parts of the plant.

In most cases these quantitative differences in pigmentation were found to be nonheritable, but one striking case is described in which there was found a strict inheritance of an extreme amount of pigmentation. A series of crosses
between this mutant and other forms is said to have given some interesting results.

Experiments with Primula sinensis, R. P. Gregory (Jour. Genet., 1 (1911), No. 2, pp. 73–132, pls. 3, figs. 2).—A study has been made of P. sinensis, particular attention being paid to heterostylism, leaf shape, habit, double flowers, characters of the eye of the flower, and color. The principal object of the investigation was to determine the inheritance of heterostylism and of color. At the same time records were kept of certain other characters, the inheritance of these for the most part being of a simple type.

A census catalogue of Irish fungi, J. Adams and G. H. Pettybridge (Proc. Roy. Irish Acad., 28 (1910), No. 4, Sect. B, pp. 129–166, map 1).—This catalogue includes a compilation of previous lists and of species from other publications on Irish fungi up to 1910. The distribution by counties of each species, an extended bibliography of Irish fungi, a list of synonyms, and an index to the genera are also given.

**FIELD CROPS.**

On the correction of results obtained in field trials, R. K. Kristensen (Tidsskr. Landbr. Plantekr., 17 (1910), No. 4, pp. 627–629).—A discussion of the value of the method of Holtmark and Larsen for correcting errors in field trials due to lack of uniformity in the soil (E. S. R., 18, p. 436).

The results of electroculture in Hedewigenkoog, Clausen (Landw. Wehnbld. Schles. Holst., 61 (1911), No. 5, pp. 83–86).—The results of electrocultural experiments with clover, wheat, and oats are reported. The data obtained do not indicate that the action of the electrical installation had any effect upon the growth of the crops.

Experiments with shelter for agricultural crops, 1910, O. Kristensen (Ber. Ribe Amts Landbofor. Harvbr. og Husmauds, 1910, pp. 20, figs. 13).—These experiments, like those of the preceding year, were conducted by Ribe county agricultural societies (Jutland). Six series of experiments were carried through with shelters of different heights and position, the crops experimented with being rye, oats, barley, rutabagas, clover, and grass.

The experiments with spring grains gave rather indefinite results, but greatly increased yields were obtained in the case of the other crops. The growth of the grasses and clovers was especially benefited by shelter. The increase in yields of hay obtained from the protected plats ranged from 12 to 50 per cent in the different trials.

Fertilizer experiments with garden crops and fruit trees are also reported.

The choice of crops for alkali land, T. H. Kearney (U. S. Dept. Agr., Farmers' Bul. 446, pp. 32).—This deals with the nature and appearance of alkali, its effect upon plant growth, and the selection of crops adapted to alkali land and to different grades of alkali. The alkali resistance of different crop plants is also discussed.

[Work with field crops at the Hawaii Station], E. V. Wilcox, W. P. Kelley, and F. G. Krauss (Hawaii Sta. Rpt. 1910, pp. 12–14, 43, 44, 51–64, pls. 6).—In plat and pot experiments it was observed that "nitrate of soda appeared to produce no beneficial effect, while ammonium sulphate was very active in promoting growth and yield of grain." Further experiments are being conducted.
FIELD CROPS.

In Hawaii "it has been shown that cotton will thrive under a wide range of rainfall, from 25 to 300 in. per year, and at a considerable variation of altitude, from sea level to 1,600 ft." Because of its upright habit of growth Caravonica cotton has proved superior to sea-island, which fruits so heavily that the branches lie on the ground, causing the bolls to rot. One sea-island plant produced 700 bolls of cotton and one tree 1,200 bolls. Pruning experiments are being conducted to determine whether the sea-island cotton can not be induced to adopt an upright habit of growth, at least during the second and subsequent years of growth. Pure strains have been propagated by means of cotton cuttings, a number of which are about to come into bearing. Propagation by means of budding has proved easy, but its economy on a commercial scale is not yet determined.

In the system of double cropping of rice followed by Chinese growers in the islands, fertilizer is applied only to the spring crop. Work has been taken up to determine the residual effect on the fall crop of this application and whether satisfactory yields may be obtained by the use of fertilizers under continuous cultivation of rice. Some results of fertilizer experiments with rice already noted (E. S. R., 20, pp. 137; 24, p. 635) are reviewed.

Among introductions from China and Japan of 100 of the most distinct types, Benkei, Miyako, Omachi, and Shinriki are described. Omachi and Shinriki excelled the old-type Japan rice, No. 153, in yield of paddy per 100 clumps and bring high market prices, since they find especial favor among the Japanese population of the islands. Some strains of the old type which are being developed are now in the seventh generation. "Increase in yield has been less noticeable than greater purity and uniformity."

Among the new varieties of rice introduced by the station, No. 19 (S. P. I., No. 12508), introduced in 1907, appears to have found favor among intelligent rice growers and is reported as well suited to the salt-marsh lands. It is regarded as desirable to combine the hard, translucent grain and heavy tillering power of this variety with the all-season cropping habits of Gold Seed. The observations made agree with those of Japanese investigators, who find that a natural hybrid among rice varieties is "of rare occurrence, notwithstanding the fact that more than 900 varieties have been grown in close proximity for several years past."

Rice rotation work with barley, cowpeas, soy beans, velvet beans, jack beans (Canavalia ensiformis), and the Chinese matting plants (Juncus effusus and Cyperus tegeliformis) has been taken up. Among 50 of the best hulled and naked Japan paddy field barleys tested, a large percentage failed to head, but 20 varieties of a very dwarf type set seed and appeared fair yielders of grain. Astragalus used for green manuring proved an entire failure. Windsor beans made a vigorous growth, but almost entirely failed to set seed. Mammoth Yellow soy beans produced 2,500 lbs. of cured fodder (including seeds), or 675 lbs. of seed per acre. Velvet beans yielded 3,420 lbs. of cured fodder or 145 lbs. of seed. Cowpeas yielded 7,200 lbs. of cured fodder or 1,117 lbs. of seed, and jack beans, 4,000 lbs. of cured fodder. In earlier trials also the cowpeas outyielded all other legumes both in green matter and seed.

In a cooperative experiment at Kunia on a light, deep, silty loam, about 600 ft. above sea level, the Seabrook variety of sea-island cotton with a yield of 212 lbs. of lint per acre excelled Caravonica, Mit Affil. and the upland variety Chinese. Low yields are attributed to a rainfall of only 22 in. for the year and a destruction of 80 per cent or less of the stand by cutworms, which necessitated much replanting. Caravonica cotton gave the greatest promise as a drought resister.
This cooperative experiment was almost duplicated by another at Waipahu, where the elevation is approximately the same but the rainfall estimated to be about 35 in. per annum. Here Mit Afifi and Seabrook produced the highest yields of lint, 101\(^2\) and 87\(^2\) lbs. per acre, respectively. Early plantings invariably excelled late plantings in yield.

At the station 30 standard cotton varieties have been planted. In a test of 1,200 buds inserted 31 per cent have made satisfactory growth, and from 10 to 60 per cent of the cuttings made took root. In minor trials under more favorable conditions the percentage of successful cuttings exceeded 80.

Eighth biennial report of the state engineer to the governor of Idaho, 1909-10, D. G. Martin (Bicn. Rpt. State Engin. Idaho, 8 (1909-10), pp. 367, figs. 4).—This is a report of work done under a cooperative agreement between the state board of land engineers and the Irrigation Investigations of this Office.

The author states in detail the soil and other conditions under which the work was done. “Throughout the investigation the amount of water producing the greatest yield is considered as the one most nearly approaching the proper amount for the soil and crop in question.” The following table states the principal results obtained:

Data secured from plots irrigated at the more successful rates.

Report of general work on the Buncombe and Transylvania test farms, R. W. Collett (Bun. N. C. Dept. Agr., 1911, Feb., Sup. pp. 7-16, figs. 4).—The Buncombe and Transylvania test farms are described and their work briefly outlined.

At the Buncombe farm the work with fertilizers "has shown, as a rule, that the soils on this farm do not respond profitably to applications of nitrogen or potash, but respond readily to applications of phosphoric acid. . . . Two extra cultivations gave 10 bu. increase of corn per acre.” Three years experimental
work has been completed on soil and crop requirements with fertilizers, variety tests of corn, wheat, oats, and potatoes, and on cultural and other tests.

Report of cooperative field and fertilizer trials in Dalarna and Norrland, 1909, S. Rhodin (K. Landtbr. Akad. Handl. och Tidskr., 49 (1910), No. 8, pp. 657-690, figs. 2).—The author gives an account of the tests conducted by county agricultural societies in northern Sweden, covering 224 different experiments with cereals, roots, pasture, and fertilizers.

Report of the Temir Experiment Field in the Turay-Ural region in the years 1907-8, S. K. Chałanow (Abs. in Zhur. Opytn. Agron. (Russ. Jour. Exp. Landw.), 11 (1910), No. 4, pp. 592-593).—The experience of the year showed that it is possible to raise cereals on the clays and sand of the Temir district, but the yields in 1907 were generally low owing to winds and weather.

[Experiments with field crops], W. R. Gourlay (Rpt. Agr. Dept. Bengal, 1910, pp. 2-6).—Brief reports are given of experiments in growing jute, cotton, flux, spineless cactus, rice, wheat, potatoes, corn, sugar cane, peanuts, and other crops.

[Fertilizer tests on grass land, including cooperative work], F. W. Taylor (New Hampshire Sta. Bul. 151, pp. 16, 17, 19, 20).—During the period 1907 to 1910, inclusive, the highest comparative average yields of hay per acre in the fertilizer tests with 12 fertilizing materials on grass land (E. S. R., 21, p. 730) were 3.115 and 2.7 tons of hay per acre, respectively, after (1) 400 lbs. and (2) 200 lbs. of nitrate of soda.

In cooperative experiments on 7 farms average yields of 4,137, 3,901, and 3,158 lbs. of hay, respectively, were secured from the nitrate, complete fertilizer, and manure plats. The check plats gave an average yield of 2,288 lbs. per acre.

Fertilizing permanent marsh pastures, Hinrichs (Deut. Landw. Presse, 38 (1911), No. 36, pp. 417, 418).—Results of fertilizer tests here reported show that ammonium sulphate gave excellent results on run-down marsh pastures, but was of no benefit on fairly productive pastures, whereas phosphoric acid and lime fertilizers did benefit the latter.

Alfalfa management, C. W. Pugsley (Nebaska Sta. Bul. 120, pp. 3-13).—The author gives “explicit instructions in regard to the seeding and care of alfalfa,” including a discussion of soils, seeding, inoculation, cultural practices, manuring, seed production, hay, and pasture.

The tillering power of barley, H. Tedin (Sveriges Utsädesför. Tidskr., 19 (1909), No. 6, pp. 292-312; abs. in Bot. Centralbl., 111 (1910), No. 10, pp. 255, 256).—The same varieties of barley were observed to vary in tillering capacity in different seasons.

Four-rowed barley in general did not tiller as strongly as the two-rowed varieties. The differences between varieties in the same class were as a rule much smaller than differences resulting from weather conditions, space between plants, and other similar factors. Close planting diminished the tillering power and the use of heavy seed as compared with small seed increased it.

Tests of some improved varieties of barley, J. J. Vaňha (Ztschr. Landw. Versuchsw. Österreich., 13 (1910), Nos. 7, pp. 633-665; 8, pp. 655-698; 9, pp. 758-785).—More than 30 varieties of barley were tested and the data secured include the weight per hectoliter, uniformity of grain, kernel weight, percentage of hull, structure of the endosperm, germinative power, protein content, and starch content. Among the varieties tested were many newly developed sorts.

At the experiment station in Brünn, a comparison was made of 85 pure-bred strains. In these the protein content ranged from 9.34 to 12.08 per cent, the starch content from 59.23 to 64.08 per cent, the thousand-kernel weight from 41.61 to 54.45 gm., and the proportion of hull from 9.31 to 12.35 per cent. The
vegetative period of these newly bred varieties ranged from 92 to 99 days, the average being 96 days.

[Variety tests of corn and cotton], J. L. Burgess (Bul. N. C. Dept. Agr., 32 (1911), No. 2, pp. 16).—Earlier work at some of these farms has been previously noted (E. S. R., 24, p. 336).

In 1910, 21 varieties of cotton were tested on the yellow loam and silt loam soils of the second bottomlands along the Roanoke and the other principal rivers in eastern North Carolina. The higher yields secured are indicated in the following table:

a Lint cotton.

Results from the Karayaz Experiment Field and the demonstration cotton fields in the Transcaucasian region, N. P. Tarat'nov (Kavkaz. Khoz., 1910, No. 6-7; abs. in Zhur. Op'ytn. Agron. (Russ. Journ. Exp. Landw.), 11 (1910), No. 4, pp. 590-592).—After the application of about 5,000 pounds of manure per dessyatina (about 33/4 tons per acre) from 300 to 400 pounds per dessyatina of corn were secured as compared with from 100 to 150 pounds per dessyatina without fertilization. The yield of alfalfa hay was similarly raised from 400 or 500 to 1,000 pounds per dessyatina, and the yield of King cotton from the United States from 30 to 40 or 45 pounds per dessyatina. Summer cereals were grown successfully, although this had been considered impossible in the Transcaucasus, except in the case of rice. Oats yielded 100 pounds per dessyatina while barley and summer wheat at times excelled winter wheat in yield. Tests indicated that more rational methods of cultivation accompanied by more moderate irrigation than locally practiced would increase the yields of grain and cotton.

Cotton growing within the British Empire, J. H. Reed (Scot. Geogr. Mag., 27 (1911), No. 5, pp. 242-257, pls. 2).—A lecture delivered before the Royal Scottish Geographical Society in Edinburgh, on March 9, 1911, in which the cotton-growing industry in the British Empire is described and reviewed to date.

Lespedeza, or Japan clover, A. D. McNair and W. B. Mercier (U. S. Dept. Agr., Farmers' Bul. 441, pp. 19, figs. 6).—This deals with the use of lespedeza for pasturage, as a farm crop, as a companion crop for Bermuda grass, red top, or oats, and in various rotations with corn, oats, cotton, soy beans, and Spanish peanuts. Directions are given for harvesting the crop for hay or seed.
The development of the root system of oats and its relation to nutritive substances, M. A. Egorov (Dvoren. XII. S’r’ëzo Russ. Est.-ISP. i Vrach. [Moscow], p. 666; abs. in Zhur. Opytn. Agron. (Russ. Jour. Exp. Landw.), 11 (1910), No. 4, pp. 602, 603).—These pages report the results of investigations of the development of the oat-root system under the conditions in the Moscow government. The tests were made in boxes and the fertilizers were mixed with the surface 7 in. of soil as it came from the field.

The author concludes that (1) the maximum depth to which the roots penetrated was 118 cm.; (2) the ratio of the roots to the total mass of the plant attains a maximum at the beginning and a minimum at the end of vegetation, being three-fourths of the total mass at the beginning and one-third at the end of vegetation; (3) readily available fertilizers considerably increase the absolute weight development of the root system but decrease its proportionate amount; and (4) there was full harmony in the development of the underground organs and those above the ground.

Systematic classification of oat varieties and the characters of the oat panicle of importance in breeding, Böhmer (Ber. Oelerhess. Gesell. Nat. u. Heilk, Giessen. Naturw. Abt., 3 (1908-9), pp. 1-87).—This article discusses the form of the kernel, its weight, size with reference to length, width, and thickness, the proportion of hull, the occurrence of twin grains, the color of the grain, pubescence in the grain, and the structure of the base of the kernel.

Cases of spontaneous disappearance of unit characters in oats, H. Nilsson-Ehle (Ztschr. Induktive Abstam. u. Vererbungslehre, 5 (1911), No. 1, pp. 1-37, pl. 1, figs. 2).—The author describes cases of the disappearance of a character as observed in plant breeding work with oats, and discusses at some length the influence which such disappearance or suppression may exert in breeding work with this plant. The facts observed indicated that forms of atavism had no connection with crossing, but were entirely spontaneous mutations, each being representative of only one factor or unit character.

Svalöf Fyris oats, H. Nilsson-Ehle (Sveriges Utsädesför. Tidskr., 21 (1911), No. 1, pp. 24-26).—The Svalöf Fyris oat is a new black variety especially adapted to the stiff clay soils of central Sweden. The author describes it and states the results of a 7 years’ test in which it outyielded all other varieties tested.

The occurrence of a perennial rice in Senegal, P. Ammann (Jour. Agr. Prot., u. scr., 21 (1911), No. 4, pp. 107-109).—The author describes a perennial rice which occurs in Senegal and reports analyses of the plant.

Three years’ experiments with fodder beets at Svalöf, I. Karlsson (Sveriges Utsädesför. Tidskr., 21 (1911), No. 2, pp. 97-105).—The yields of roots and of dry matter obtained in trials of 4 Svalöf mangels during the period 1908-1910 are reported. Bortfelder and Yellow Tankard excelled Oestersundom and Gray Stone in yield.

The relation between the dry substance of beet leaves and the sugar-building capacity of the plant, K. Andrlik and J. Urban (Ztschr. Zucker-indus. Böhmen, 34 (1910), No. 6, pp. 335-345).—It was found that the relation of the weight of the dry matter in the leaves to the quantity of sugar stored in the root is not constant during growth or at the time of harvesting.

At the beginning of the vegetative period the ratio ranges from about 0.5 to 1:1, increasing as growth proceeds and reaching from 2 to 4:1 at maturity.
Some plants when harvested show a wide ratio, while others, especially those low in sugar content, show a narrow one.

The sugar-building capacity of the leaves reaches its maximum about the middle of July, but this period is somewhat dependent on the time the seed germinates. When the leaves are removed about July 1 the consequent new growth will show a greater sugar-elaborating capacity than the older leaves. When the sugar formation is at its maximum, 100 gm. of dry matter in the foliage elaborates from 4.3 to 4.8 gm. of sugar per day.

The average quantity of sugar formed showed little variation during any particular season among the beets grown from different kinds of seed, but the various seasons showed considerable differences in this regard due to the differences in the conditions of growth. In 1906, it was observed that 100 kg. of dry matter in the leaves produced from 2.5 to 2.6 gm. of sugar per day, while in 1907 the daily production reached 3 gm.

Notes on classification and examination of the canes at present indigenous to Bengal, C. S. Taylor (Dept. Agr. Bengal, Dept. Rec., 1910, No. 3, pp. 21, fig. 1).—The author describes a number of cane varieties and outlines the chemical work undertaken on them. He presents in tabular form data on the comparative juice extraction of the varieties and the results obtained in the estimation of the fiber and saccharose in their megass.

Cane sugar, N. Deerr (Manchester, England, 1911, pp. XV+592, pls. 23, figs. 239).—This is "a text-book on the agriculture of the sugar cane, the manufacture of cane sugar, and the analysis of sugar-house products, together with a chapter on the fermentation of molasses." About 170 pages are devoted to the agriculture involved, but the major portion of the work is devoted to the technical and manufacturing aspects of the subject. Reference lists follow the several chapters, while the preface contains book lists on the agricultural, manufacturing, chemical, analytical, and other phases of the subject, and a list of journals devoted to the sugar industry.

Thickness of sowing summer wheat, depth, and time of plowing under it, A. Aleksandrovich (Khutoryanik, 1909, No. 50; abs. in Zhur. Opytn. Agron. (Russ. Jour. Exp. Landw.), 11 (1910), No. 4, pp. 395, 596).—The author reports results obtained at the Buguruslan experiment field in the Samara government. Four years' data show that plowing 7 and 10½ in. deep in August resulted in yields of 85 and 89 poods per dessyatina (1,135.60 and 1,180.64 lbs. per acre) of grain, respectively. September plowing to the same depths was followed by yields of 81 and 88 poods per dessyatina, respectively. Sowings of 4, 5, and 6 poods per dessyatina were followed by yields of 89, 106, and 111 poods per dessyatina, respectively.

The influence of nitrate of soda applied at different times on the structure of the endosperm and on the protein content of wheat, F. Moertlbauer (Illus. Landw. Ztg., 30 (1910), No. 98, pp. 903, 904).—The results of experiments showed that very early top-dressings of nitrate of soda on winter wheat decreased the flintiness of the kernel, while late applications increased this property. In every case where part of the quantity was applied late the hardness of the grain was improved. A top-dressing given when the heads began to form invariably produced a marked increase in the degree of flintiness. Experiments with spring wheat gave very similar results. The dry matter content of the grain was only slightly increased as a result of early applications of the nitrate. The protein content in general varied with the flintiness of the grain of both winter and spring wheat; the correlation, however, not being so definite that the degree of flintiness could serve as a reliable index to the protein content. The results seemed to indicate further that flintiness is not necessarily the only condition which determines the protein content.
Utilization of the nutritive substances from manure by oats and wheat, A. V. Klucharev (Dnever. XII. St'vzda Russ. Est.-Isp. i Vrach. [Moscow], p. 665; abs. in Zhur. Opvy. Agron. (Russ. Jour. Exp!. Landw.), 11 (1910), No. 4, p. 602).—In sand culture tests manure was compared with other sources of nitrogen, phosphoric acid, and potash.

Three years' experiments show, in part, that the lowest yields were obtained from the vessels with manure without other nitrogen. On introducing manure in place of potash and phosphoric acid the yields were no less than in the normal vessels, and in some cases even higher. Up to 60 per cent of the phosphoric acid was utilized, and up to 93 per cent of the potash as compared with 24 per cent or less of the nitrogen in the manure.

Spraying to eradicate dandelions from lawns, G. T. French (New York State Sta. Bul. 335, pp. 35-43).—In 1909 a strip of lawn infested with dandelions was sprayed 6 times between April 23 and September 24 with iron sulphate dissolved at the rate of 1.5 lbs. in each gallon of water. The strip was again sprayed 6 times between April 15 and June 29, 1910, with a solution of 2 lbs. of the sulphate per gallon of water. The blooming of the dandelions was entirely prevented and many of the plants were killed, but there were still 1,085 live dandelions on 1,000 sq. ft. of the lawn in July, 1910, when treatment was discontinued for fear of ruining the lawn. After all but one of the applications the area sprayed was blackened for several days. The grass did not appear materially injured during 1909, but in 1910 the stronger solution and more frequent applications considerably injured it.

The author attributes the lack of success to the vitality of the dandelion roots. To test this, one plant was cut off 7 times and another 8 times below the crown before being finally killed. He briefly summarizes some results of work already noted (E. S. R. 15, p. 360; 19, p. 1036; 21, pp. 635, 737; 23, p. 733).

Some investigations of the appearance and longevity of weed seeds, K. Dorph-Petersen (Tidsskr. Landbr. Plantavl, 17 (1910), No. 4, pp. 584-626).—The investigations here reported were conducted at the Danish seed control station during 1896-1910. The extensive material presented shows that commercial seed, especially clover and grass seed, often contain many thousand weed seeds per kilogram. These seeds possess a good germinating power and often germinate slowly in the course of several years. A large number of weed seeds retain their germinating power for a long period whether in a dry condition or in the ground. It is shown that many weed seeds are not destroyed by the milling process or by passing through the alimentary canal of cattle, swine, or poultry.

Weeds of Ontario, J. E. Howitt (Ontario Dept. Agr. Bul. 188, 1911, pp. 144, figs. 106).—Brief discussions of weeds and weed seeds and of sections of the Canadian Seed Control Act are followed by popular descriptions of numerous common weeds and notes on their eradication.

Weeds and their destruction, H. C. Long (Trans. Highland and Agr. Soc. Scot., 5. scr., 23 (1911), pp. 45-83, figs. 20).—Descriptions of the worst weeds of Scotland's grass and arable lands are accompanied by directions for their control or eradication.

HORTICULTURE.

Horticultural information.—How to obtain it, R. S. Pickert et al. (New Hampshire Sta. Circ. 11, pp. 2-8).—This circular contains suggestions relative to the sources of horticultural information, together with lists of books, bul-
letins, and periodicals prepared by the members of the department on general horticultural subjects, fruit culture, vegetable gardening, floriculture, greenhouse management, and landscape gardening.

Annual and biennial garden plants, A. E. Speer (London, 1911, pp. XX+256, pls. 54).—In this popular English work the annual and biennial garden plants are arranged alphabetically and briefly considered relative to their value, uses, and culture.

Market gardening, II, R. L. Watts (Penn. Dept. Agr. Bul. 201, 1910, pp. 85, pls. 29).—The subject matter of this bulletin, which supersedes Bulletin 147 of the same series (E. S. R., 18, p. S26), has been brought up to date by the inclusion of newer methods of culture and improvements of methods that have been in common use. The arrangement of the material is quite similar to that in the previous bulletin.

The small garden useful, A. C. Curtis (London, 1909, pp. VII+206, pls. 6).—A popular treatise on vegetable gardening.

Root and stem vegetables, A. Dean (London and Edinburgh [1911], pp. VIII+114, pls. 8).—The subject matter of this treatise on vegetable growing is based upon the author's long experience as a vegetable grower. The work is confined to vegetables that yield food in the shape of roots, bulbs, tubers, or blanched stems. Chapters on mushroom culture, the preparation of vegetables for exhibition, and a calendar of operations are also included.

Cauliflower and Brussels sprouts on Long Island, L. B. Judson (New York Cornell Sta. Bul. 292, pp. 229-286, figs. 28).—This bulletin comprises the results of a study of the cauliflower and Brussels sprouts industries on Long Island.

Part 1 deals with the cauliflower and discusses the history and extent of the industry, preparing the soil, rotation, seed, raising the plants, transplanting, fertilization and cultivation, tying, cutting and trimming, packing, storing, yields, prices, profits, and shipping conditions, including an account of the Long Island Cauliflower Association. Consideration is also given to insect pests and diseases, including bibliographies on insect enemies and diseases of cole crops.

Part 2 contains similar cultural details for Brussels sprouts. The bulletin concludes with a general bibliography for each of these crops.

Satisfactory progress has been made in propagating avocados, especially by budding, the greatest difficulty with this being the forcing them into growth. The sap ooze:s out from the incision, evaporates, and leaves a crystalline deposit which frequently covers the whole bud and sometimes the whole bud shield. This difficulty has been largely overcome by wrapping the whole of the stock in the region of the incision, thus preventing evaporation. It has been found inadvisable to lop the stock immediately after the bud has become united, since the stock is apt to dry back to the bud and below it before the latter has started into growth. Instead of lopping, the stock may be partly or completely girdled at a point several inches above the bud, only a narrow ring of the bark being removed.

Inarching is being successfully used for certain types of propagation, such as the testing out of seedlings on old trees. Partially successful results in making rooted cuttings of avocados were secured by packing the cuttings in moist sphagnum moss for several weeks before placing them in the propagating bench. Well-matured wood with gray bark proved most promising in this work.

Studies have been made of a large number of varieties of avocados for the purpose of ascertaining their merits for commercial or home production. Four of these varieties of particular merit are here described.
The methods of propagating mangoes previously noted (E. S. R., 22, p. 642) have continued to give good results, and the continued tests of the possibility of transplanting the mango trees show that this operation is relatively simple and successful in a majority of cases. A list is given of the varieties of mangoes now growing at the station.

Observations made on papayas show that both dioecious and monoecious types with various intermediate forms occur in Hawaii. Only a few fruits are borne on the staminate trees of the dioecious type, whereas the monoecious type bears fruit on every tree. It is impossible to distinguish the pistillate and staminate trees at an early age, hence in orchards planted with the dioecious type a certain percentage of the trees will prove to be males and therefore sterile. It seems best to use only the monoecious type for breeding and selection purposes. The work of breeding papayas has been commenced and there is evidence that ultimately a strain will be produced which will come true from seed.

Several new varieties of oranges, pomelos, and lemons were introduced during the year. Successful trial shipments of sweet potatoes to San Francisco were made. It appears to be a good practice to make at least one planting of sweet potatoes for shipment to California some time during the interval between the first of May and the middle of July, when the local potatoes are off the market. Yellow-flesh varieties were preferred.

Brief notes are given on the mangosteen (Garcinia mangostana), litchi (Nephelium litchi), and Curissa arduiana, a South African fruiting shrub introduced by this Department. Experiments in growing deciduous fruits at higher altitudes indicate that the outlook is promising for the production of apples, peaches, and grapes.

Tree tanglefoot was used on the deciduous plantings as well as on the station trees for the purpose of preventing ants, cutworms, and other injurious insects from ascending the trees. Under certain conditions it has proved quite effective. Where it has been allowed to remain on peach trees for many months, however, the trees were killed. It is recommended that with peach trees particularly the tanglefoot should not be applied directly to the bark but rather to a band of cheap cotton which has previously been dipped in hot paraffin.

[Notes on horticultural investigations], B. S. PICKETT (New Hampshire Sta. Bul. 151, pp. 27-29).—A brief statement of progress made in horticultural investigations at the station during the biennial period ended November 1, 1910.

The effect of various cultivation and fertilizer treatments on the formation of fruit buds is being studied in an apple orchard consisting of some 300 trees. The results noted in 1910, or during the third season, are tabulated showing the fertilizer, cover crop, and cultural treatments, and the percentages of full bloom on each plant. Generally speaking, the plats which were cultivated each year have made the most wood growth and the sod plats the least. Thus far the fertilizers do not appear to have influenced the rate of wood growth.

The rejuvenation of orchards.—Report of spraying experiments in southeastern Ohio, 1910. F. H. BALLOU (Ohio Sta. Bul. 224, pp. 117-150, figs. 20).—Following demonstration experiments conducted in 1909 by the station in Washington County on the control of apple scab with Bordeaux mixture (E. S. R., 24, p. 544), this bulletin contains the results of spraying operations conducted by the station and by individual growers during the season of 1910.

In the experiments conducted by the station lime-sulphur was used under many conditions of soil and elevation and on quite a number of the better-known varieties of apples. As compared with Bordeaux of various strengths, the results warranted the substitution of lime-sulphur for Bordeaux mixture. The
Bordeaux injury was particularly prevalent during the season, this fact being attributed to the extreme cold of April and May after a summerlike March. The orchards situated on the thinner, poorer soils suffered extremely, both from the cold and from Bordeaux injury. With orchards situated on fertile soils and with varieties not especially subject to spray injury, there was less difference in favor of lime-sulphur, although the latter spray was superior to a greater or lesser degree in all the tests. The lime-sulphur application appeared to stimulate the growth as well as control the scab. In general the extent of injury by Bordeaux was found to correspond to the lack of vigor of the trees on which it is used.

The results, as a whole, of the spraying work in the county showed that 117 orchards which have yielded an annual average total of 4,446 bu., yielded in 1910, 63,700 bu.

Suggestions for spraying, W. E. Rumsey, N. J. Giddings, and A. L. Dacy (West Virginia Sta. Bul. 133, pp. 5-26, figs. 5).—The purpose of this bulletin is to present a summary of data as to the best methods thus far developed by scientific investigators and practical orchardists for fighting plant diseases and injurious insects. It discusses the equipment needed for spraying and gives a spray calendar for the control of the more common diseases and insects of the apple, pear, peach, plum, cherry, grape, and potato, together with information relative to the formulas and preparation of spray materials.

Spraying peaches for the control of brown-rot, scab, and curculio, W. M. Scott and A. L. Quaintance (U. S. Dept. Agr., Farmers' Bul. 440, pp. 49, figs. 14).—Experiments begun by the Bureau of Plant Industry in 1907 and subsequently continued on a larger scale in different parts of the eastern United States have established the effectiveness of the self-boiled lime-sulphur wash for the control of peach brown-rot and scab (E. S. R., 23, p. 150). Further experiments conducted jointly by the Bureau of Plant Industry and the Bureau of Entomology in 1909 have shown that the curculio may be controlled at the same time at a small cost by adding lead arsenate to the lime-sulphur mixture (E. S. R., 23, pp. 59, 150). Similar cooperative experiments and demonstrations were conducted in 1910, and the results as here given further establish the effectiveness of the combined self-boiled lime-sulphur lead arsenate spray.

The brown-rot, scab, and curculio are discussed with reference to their life history in relation to the peach, including observations with the plum curculio. With the results of the 4 years' experiments as a basis practical information is given relative to the preparation and use of the spray, including a schedule of application for early, midseason, and late varieties.

In addition to cooperative spraying experiments conducted by the Department in Georgia and in West Virginia considerable use was made of the combined mixture by peach orchardists in a number of eastern States, the results having been uniformly satisfactory. Aside from the actual control of the curculio, scab, and brown-rot, the sprayed peaches are as a rule somewhat larger, much more highly colored, and firmer than unsprayed fruit. The observations and experiments also go to show that when used as a summer spray the self-boiled lime-sulphur wash has a material effect on the control of scale insects which may be present on the trees, especially the San José scale. This effectiveness consists largely in bringing about the death of young scales. Further observations are necessary to determine the extent of this benefit, but it is suggested that in peach orchards regularly sprayed with the lime-sulphur wash during the summer, the usual winter treatment for San José scale may not be required so often.

Although no material injury has resulted from 3 applications of lead arsenate in combination with self-boiled lime-sulphur, only 2 applications of the com-
bined treatment are recommended, unless the curculio is very destructive, since a third treatment would increase the danger of injury. Arsenate of lead increases the color of the fruit notably and this increase in color from the 2 applications of the combined mixture improves the appearance of the fruit, whereas the use of arsenate of lead alone creates an excessive coloration, which is often followed by brown sunken spots and more or less extensive cracking of the skin.

From the experience of the authors, it is concluded that in most of the peach orchards of the eastern United States an increase per tree of at least ½ bu. of good merchantable fruit may be obtained from spraying at a cost of from 3 to 5 cts.

Apple growing in New England.—IV, Orchard management, C. D. Jarvis (Connecticut Storrs Sta. Bul. 66, pp. 217–263, figs. 35).—The preceding bulletin of this series on apple growing in New England (E. S. R., 23, p. 242) considers the subject of starting young orchards. The present bulletin discusses the various phases of orchard management, including general considerations relative to specialization and diversified farming and the limiting factors in orcharding, cultural systems, soil management, fertilizing, pruning, spraying, and thinning. The bulletin is intended for the diversified farmer more than for the specialized apple grower.

Fertilization and cultural methods for apple orchards, J. P. Stewart (Penn. Dept. Agr. Bul. 197, 1910, pp. 94–112).—The subject matter of this paper has been noted from another source (E. S. R., 23, p. 341).

Banana culture, R. Runge (Mitt. Justus Perthes' Geogr. Amt., Ergänzungsh. 160, pp. VIII+117, pls. 14, map 1).—In this work the banana is considered relative to its geographic distribution, industrial importance, and cultural history in the various producing countries.

Biometric investigations on a graft hybrid between the pear and quince, L. Daniel (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 18, pp. 1186–1188).—This consists of a biometric study of the leaf notches of a graft hybrid between the pear and quince as compared with the leaves of a pear of the same variety as the scion growing on its own roots. Measurements of 1,034 leaves were made.

The data show the leaf characters to be more or less intermediate between the parent stock and the parent scion.

A study of the improvement of citrus fruits through bud selection, A. D. Shamel (U. S. Dept. Agr., Bul. Plant Indus. Circ. 77, pp. 19, figs. 5).—This circular has been prepared with a view to supplying information to investigators and fruit growers in different parts of the United States regarding the methods of work used in investigating the variation in the yield of citrus fruits in California. No attempt is made to present definite results. The investigation has for its object the demonstration of methods for the elimination of unprofitable trees in citrus groves and the production of reliable select citrus trees for new plantings.

The various phases discussed include varieties of citrus fruits selected for performance records, location of performance-record plats, selection of individual trees, tree markers and numbers, performance records, photographs, picking, grading and sizing, counting and weighing, record blanks, arrangement of data and photographs, note taking, citrus improvement clubs, importance of uniformly productive trees, and the value of reliable select trees.

The cultivation of guavas near Poona, Dharwar, and Limbgaon, L. B. Kulkarni (Dept. Agr. Bombay Bul. 40, 1911, pp. 12, pls. 4).—Brief descriptive accounts are given of the cultural methods employed in the above-named re-
gions, including data relative to the cost of establishing and maintaining guava plantations.

Lemon blossoms and why they fall off, J. E. Cort (Col. Cult., 36 (1911), No. 23, p. 683, figs. 4).—A preliminary study of the factors influencing the setting of lemons leads the author to conclude that, other conditions being equal, the annual dropping of blossoms and small lemons in May is due generally to an overproduction of blossoms and fruit rather than to any pathological cause. Experiments conducted this spring indicate that pollination of the blossoms of lemons is not necessary for the setting of fruit and that the presence of bees in lemon orchards may cause the lemon to contain too many seeds by bringing about pollination and fertilization.

A study of the growth of lemons leads the author to conclude that, contrary to a common opinion among lemon growers, the lemons fruit on new growth of the season instead of on old wood. The stems or peduncles growing on old, inferior limbs are classed as shortened branches bearing small foliar bracts which represent abortive leaves.

In connection with the study of manganese in the soil as affecting the growth of pineapples (E. S. R., 22, p. 240) experiments were made with a number of field crops, garden vegetables, and fruit trees to determine whether they could be grown in rotation with pineapples or replace pineapples in the manganiferous soils. The manganese invariably caused a yellowing of all the leaves and a premature falling of the lower leaves on all plants tested, the ultimate outcome being a decidedly stunted growth and small yield. The root system in manganiferous soils is peculiar in the length and fineness of the small roots. This is attributed to the lack of resistance in the soils, which remain loose like ashes no matter how frequently irrigated.

In the fertilizer experiments being conducted with pineapples, the plants treated with dried blood or ammonium sulphate, superphosphate or reverted phosphate, and sulphate of potash have from the first greatly exceeded all others. Although the yields were not entirely satisfactory, these results suggest a possible treatment for soils that contain limited quantities of manganese. Areas that contain 4 per cent or more of manganese are ill suited to pineapple growing. The soil appears to be greatly benefited by the application of soluble phosphates, whereas basic slag produces an increased tendency to a yellowing of the plants as well as reduced yield. It is suggested that soluble phosphates may render the manganiferous salts in the soil less soluble. The addition of lime, on the other hand, results in the development of a more intense yellow color in the plant and its subsequent failure to produce fruit. The studies of manganese relative to its solubility, its relation to other fertilizers, and its physiological functions, etc., are to be continued.

For the purpose of determining some of the facts regarding the composition of pineapples as influenced by the stage of ripeness at which they were gathered, analyses were made and are here reported of fruit normally ripened, just before the beginning of the ripening process, ripened after being picked green, when about one-fourth ripe, and when half ripe. The results show that the sugar content of the fruit is derived exclusively from the leaves of the plant and does not increase after the fruit has been removed from the plant. In general it was found that the acidity increases with the sugar content and that the average of the total sugars is about equal to that of pineapples from Florida (E. S. R., 22, p. 640) and the West Indies. The sugar content of green
fruits or fruits ripened after being picked too green is about 2 or 3 per cent, while that of fruits ripened on the plants ranges from 9 to 15 per cent. There is no increase in the sugar content of the fruit picked too green from the time it is removed from the plant, and analysis showed no substance which could be changed into sugar during the ripening process, which in fruits picked green appears to consist largely in a softening of the tissues. In order to obtain a good flavor in fruits, they should not be picked until they have turned yellow at the base to the extent of one-fourth their length.

The graft stocks in dry and lime soils, P. Gervais (Prog. Agr. et Vit. (Ed. l'Est-Centre), 32 (1911), No. 21, pp. 654-658).—In this paper, presented at the International Congress of Agriculture, Madrid, 1911, the author points out that the results of experiments, observations, and plantings in France and elsewhere have shown the hybrids of Vinifera × Berlandieri to be the graft stocks par excellence for dry and lime soils by reason of their faculties of soil adaptation and of affinity for various kinds of grapes.

Report on the distribution of the grape phylloxera (Phylloxera vastatrix) in Austria in 1907, 1908, and 1909, as well as on the work and results secured in reestablishing infested vineyards, together with the laws, orders, and exemptions dealing with the phylloxera (Ber. Verbr. Reblaus Österr., 1907-1909, pp. 313, map 1).—This report covers the various grape growing centers of Austria.

Evolution of the tea trade, J. J. MacFarlane (Tea and Coffee Trade Jour., 20 (1911), No. 6, pp. 535-540, maps 4).—A statistical study of the world's tea trade, with data showing the net imports and consumption per capita for the principal importing countries during the period 1900 to 1910.

Pecans, P. F. Williams (Bul. Agr. Dept. Ala., 1911, No. 41, pp. 68, pls. 7, figs. 4).—This is a revision of a previous bulletin of the same series (E. S. R., 22, p. 737). The additional phases herein discussed include cultivation, harvesting, marketing, and storing the ground. A number of plates have been added.

The pecan in Alabama, P. F. Williams (Alabama Col. Sta. Bul. 155, pp. 68, pls. 7, figs. 4).—An edition as a station publication of the bulletin noted above.

Daffodils, J. Jacob (London and Edinburgh [1911], pp. IX+115, pls. 8).—A treatise on daffodil culture. The successive chapters discuss the daffodil in books, history, botany and physiology, cultivation, changing bulbs from one garden to another, propagation, raising new varieties by crossbreeding, enemies, diseases, poisons, classification. Royal Horticultural Society classifications, lists of varieties for different purposes, daffodil shows, and a calendar of operations.

The use of acid soils for raising seedlings of the Mayflower (Epigaea repens), F. V. Coville (Science, n. ser., 33 (1911), No. 853, pp. 711, 712).—The development of a system of cultivating the swamp blueberry (Vaccinium corymbosum) by the use of acid soils (E. S. R., 24, p. 433) suggested that a similar method might succeed with the trailing arbutus because the two plants have the same natural habitat and also because the arbutus has a symbiotic root fungus similar to that found on blueberry roots.

Seeds of the trailing arbutus were procured in New Hampshire in July, 1909, and sown in a mixture of kalmia peat, sand, and sphagnum. They germinate in August and after successive transplantings in an acid soil consisting of 3 parts kalmia peat by bulk and 1 part clean sand, the plants begin to form their flowering buds in August, 1910. The larger plants more than filled a 5-in. pot. They were left outdoors during the winter, were brought into a
cool greenhouse in March, and came into flower in a few days. The flowers had the characteristic color and fragrance of wild ones and were of large size.

Plants kept in a greenhouse all winter flowered only sparingly but permitted of a study of the fruit which is not a loculicidal capsule as generally described. Its style of dehiscence is given as "septicidally or rather marginidally sep-tifragal." In examples of perfect development the wall of the fruit while still green and herbaceous splits along the cell partitions into 5 valves which spread backward into a 5-pointed rosette, exposing the white, fleshy, succulent interior with the minute brown seeds dotted over its surface. The fleshy part, which resembles an unripe strawberry, is about ¼ in. in diameter and consists of the whole interior of the fruit, axis, and dissepiments as well as placenta.

The small garden beautiful, A. C. CURTIS (London, 1909, rev. ed., pp. X + 155, pls. 25, fig. 1).—A popular treatise on garden design, discussing the ground work, the herbaceous border, hardy perennial plants and bulbs, small rock and water gardens, roses, shrubs and climbers, and the small kitchen garden. A number of garden plans are included in the illustrations.

The suburban garden guide: Planting time-tables, how and when to spray, what to grow—and how, P. T. BARNES (New York, Harrisburg, Pa., and Chicago, 1911, pp. 64).—A concise popular handbook of information.

Report of the Board of Metropolitan Park Commissioners (Rpt. [Mass.]. Bd. Metropol. Park Comrs., 18 (1910), pp. 158, pls. 7, maps 6).—This is a report of the Metropolitan Park Commissioners of the Commonwealth of Massachusetts. It comprises the reports of the commissioners, the secretary, and the engineer, and a financial statement for the year. The reports of work conducted on various projects are appended.

**FORESTRY.**

The commercial woods of the United States and their uses, G. T. SURFACE (Bul. Geogr. Soc. Philadelphia, 8 (1910), No. 3, pp. 20–34, pls. 5).—The author outlines briefly the geographic timber belts and the important merchantable species occurring in each belt, points out the factors governing the adaptation and value of wood, and indicates the kinds of wood suitable for various classes of construction.

The aspens: Their growth and management, W. G. WEIGLE and E. H. FROTHINGHAM (U. S. Dept. Agr., Forest Serv. Bul. 93, pp. 35).—This bulletin presents important facts concerning the aspens and suggests methods by which aspen stands may be profitably managed.

The phases discussed include the species of aspens and how to distinguish them, the wood and its use, pulp-wood logging, general and commercial range of the aspen, climatic, soil, and moisture requirements of the tree, its growth, size, and longevity, susceptibility to injury, and reproduction by seed and by suckers. Aspen stands are discussed relative to their origin, development, and decadence in the Northeast and their management, both as temporary and permanent crops. Volume tables for aspen are appended. The chief uses of the aspen at present are for paper, pulp, excelsior, and fuel.

Properties and uses of Douglas fir, MCG. CLINE and J. B. KNAPP (U. S. Dept. Agr., Forest Serv. Bul. 88, pp. 75, pls. 3, dgm. 15).—Since 1903 the Forest Service has been making a comprehensive series of tests to determine the mechanical properties of the commercial woods of the United States, general summaries of the results secured having been previously noted (E. S. R., 19, p. 651).

Part 1 of this bulletin, which deals with the mechanical properties of Douglas fir, is based on tests made in cooperation with the University of California,
Berkeley, Cal., and the University of Oregon, Eugene, Oreg. The data are presented in numerous tables and diagrams and further discussed under the following headings: General results of tests; methods of test; bending tests; tests in compression parallel to grain; tests in compression perpendicular to grain; shearing tests; average results of tests and variation of results; relation of physical characteristics to mechanical properties, including a discussion of color, weight, proportion of summerwood, rate of growth, and various defects; failure under compression, cross-grain tension, tension, and horizontal shear; grading rules and specifications, including a discussion of these in their relation to the results of the mechanical tests; and seasoning, including the distribution of moisture in green and air-seasoned specimens, rate of seasoning, shrinkage during seasoning, effect of seasoning on strength, and failure in seasoned timber. The tests as a whole are summarized. The results are of special interest to the users of structural timber.

Part 2, which deals with the commercial uses of the timber, is based on information furnished by lumber manufacturers and other industrial concerns that use Douglas fir. The special features given are relative to its preparation and utilization for piling, poles, mine timbers, railway ties, bridge and trestle timbers, timber for car construction, all kinds of lumber for houses, material for the furniture maker and boat builder, cooperage, tanks, paving blocks, boxes, pulpwod, fuel, and miscellaneous commodities, including wood for distillation.

The Eucalyptus in Texas. J. H. ARBENZ (Texas Dept. Agr. Bul., n. ser., 1911, No. 8, pp. 9, figs. 5).—A brief statement is given relative to the behavior of different species of eucalypts which have been tested in a number of places in southwest Texas. During the severe weather in January, 1911, those trees less than 3 years old were in most cases killed to the ground, the temperature having ranged all the way from 12 to 20°F. With trees 4 years and more of age, the greater number of the lateral branches were killed but the main trunks escaped.

Red gum (Eucalyptus rostrata) has been more widely planted than any other variety and is considered a standard variety for south Texas.

Gum and resin yielding plants, H. J. DE CORDEMOY (Les Plantes a Gommes et à Résines. Paris, 1911, pp. XIV+312, figs. 15).—A handbook of information relative to the botany and exploitation of the various gum, resin, and gum-resin yielding plants, together with the chemistry of the various exudations, including information relative to their principal properties and characters and their application in the industries and arts.

[Rubber investigations], E. V. WILCOX (Hawaii Sta. Rpt. 1910, pp. 17, 18).—Visits to all of the commercial rubber plantings in Hawaii during the year revealed a satisfactory growth in the plantations located in various altitudes up to 1,400 ft., above which elevation no commercial plantings have been made. Ceara rubber grows much more rapidly than Hevea rubber, and it remains to be determined whether the ultimate yield of Hevea will be sufficiently large to make up for its slowness of growth. Trees which have received clean cultivation since planting are larger at 2 years of age than 6-year-old trees which have not been cultivated. Cultivation appears to be of particular value in aerating the soil.

Fustic wood: Its substitutes and adulterants, G. B. SUDWORTH and C. D. MELL (U. S. Dept. Agr., Forest Serv. Circ. 184, pp. 14, figs. 1).—The wood of the fustic tree (Chlorophora tinctoria), a native of the West Indies and tropical America, which yields valuable yellow, brown, and green dyestuffs, is frequently adulterated with or replaced by different woods, of which the more important are the smoke tree (Cotinus coticus), osage orange (Toxylon
pomiferaum), and several species of the prickly ash (Xanthoxylum). This circular points out the distinguishing characteristics of genuine fustic wood and of its principal substitutes in order that consumers may readily distinguish the real from the spurious article. A full description of the microscopic structure of fustic wood is presented as a guide for the detection of possible new and at present unknown substitutes.

Preservative treatment of poles, compiled by W. H. Kempler (U. S. Dept. Agr., Forest Serv. Bul. 83, pp. 55, pls. 4, figs. 11).—This bulletin summarizes the results published in previous Forest Service circulars (E. S. R., 20, p. 48), and presents additional data and information gained by the more recent investigations, especially those by O. T. Swan.

The subject matter is discussed under the following general headings: General principles of wood preservation; Forest Service investigations; résumé of projects; results of seasoning tests; brush method and open-tank process of treating poles; advantages and limitations of the open-tank process; results of treatments by species, including chestnut, southern and northern white cedar, western red cedar; western yellow, lodgepole, and loblolly pine, and cypress; design and operation of pole treating plants; increased life afforded by preservative treatment; financial saving; relation of preservative treatments to pole specifications; and growth and form of poles. The results of the investigations as a whole are summarized.

The appendix contains a report on an inspection of experimental southern white cedar and chestnut poles previously treated by the Forest Service in cooperation with the Southern Bell Telephone and Telegraph Company (E. S. R., 19, p. 243). In addition to a summary and discussion of the condition of the poles under the various treatments, analyses are given of the preservatives used. Detailed tables and curves showing the rate of seasoning of poles are also appended.

Fourth annual report on forest conditions in Ohio (Ohio Stu. Bul. 223, pp. 57–116, figs. 19).—This comprises a brief introductory report by C. E. Thorne (pp. 57–59), a report of the consulting forester, by W. J. Green (pp. 60–62), in which the station's policy in cooperating with public institutions and cities in the study and testing of ornamental trees, shrubs, and shade trees is outlined, and a report of the forester, by E. Secrest (pp. 63–116).

As noted in the report of the forester the chief lines of work in which the station has been active during the year ended October 1, 1910, are as follows: Cooperation with public institutions possessing land as to the management of timber tracts and the establishment of experimental and demonstration plantations; cooperation with private owners in the improvement of the farm woodlot and in various operations of reforestation; and the establishment of nurseries for experimental purposes and the distribution of forest-tree seedlings in connection with the various operations of cooperative work. The forest survey of the State was conducted as in previous years (E. S. R. 23, p. 44), 10 additional counties being surveyed during the past season. The results of the survey are summarized. Educational work was conducted through various agencies.

Among the chief destructive agencies of forests in Ohio particular attention is called to the European pine blister rust (Peridermium strobi), which was recently introduced from Germany (E. S. R., 21, p. 644), and has been found occurring in 2 Ohio nurseries within the past year.

Among the recommendations suggested for the improvement of forest conditions in Ohio are a better system of fire protection, including a fire warden service, the establishment of state forest reserves, the regulation of stream flow, protection and jurisdiction of shade trees, and assistance in the establish-
FORESTRY.

345

ment of municipal forest parks. The text of the laws of Ohio relating to for-

estry are appended.

Review of forest administration in British India for the year 1908–9, with a quinquennial summary, F. B. BRYANT (Rev. Forest Admin. Brit. India, 1908–9, pp. 58, maps 2).—This is the customary annual progress report on the constitution, management, financial results, and administration of the state forests in the various Provinces of British India for the year ended June 30, 1909.

All the important data relative to forest areas, various forest operations, forest products, yields, returns, etc., are appended in tabular form, including summarized data showing the financial returns for the quinquennial periods from 1873–4 to 1907–8. Maps are also appended showing the distribution of forests and waste lands as well as the progress of forest surveys and working plans in India.

The total area of forest lands under control of the forest department was in-

creased during the year by 3,965 square miles to a total of 241,774 square miles, or 24.5 per cent of the area of British India. In addition some 12,193 square miles of forest lands are controlled by other departments. Of the total area of reserves, 46,332 square miles, or 49 per cent, was under systematic fire protection.

Experiments carried out by the forest department have shown that Para rubber (Hevea brasiliensis) can be successfully grown in southern Burma and Ficus elastica in Assam. Little success has attended the efforts to grow these and other rubber-producing species in other parts of India.

The gross revenue for the year was 25,456,739 rupees (88,258,049.30), the gross expenditure 14,726,034 rupees (4,777,567.21), and the surplus over ex-

pendsiture directly chargeable to revenue was 17,820,061 rupees (5,781,462.39).

Progress report of forest administration in the Province of Eastern Bengal and Assam for the year 1909–10, A. V. MONRO, H. CARTER, and W. E. MELLOR (Rpt. Forest Admin. East, Bengal and Assam, 1909–10, pp. 16+15+77+3, map 1).—This is the usual progress report relative to the con-

stitution, management, financial results, and administration of the state forests in the Western and Eastern Circles, Eastern Bengal, and Assam, for the year ended June 30, 1910.

All the important data relative to forest areas, various forest operations, forest products, revenues, returns, etc., are appended in tabular form.

The need of afforestation in the United Kingdom of Great Britain and Ireland, A. D. BŁASZECK (Sci. Prog. Twentieth Cent., 5 (1911), No. 20, pp. 611–641).—This consists of a résumé of the history of forestry in Great Britain, together with a discussion of forestry in relation to the employment of land, capital, and labor and the indirect effects produced. The paper concludes with suggestions for the improvement of existing forests.

Suggestions for woodlot owners in Maine, J. M. BRISCOE (Maine Sta. Doc. 402, pp. 27, figs. 8).—The author considers that for the individual owner of woodland in Maine there is no tree better suited either for regeneration by methods of natural reproduction or for planting than the white pine. The chief characteristics of this species are described in detail and directions are given for the best methods of treatment in the development of pure stands and of stands mixed with hard woods.

The farmer’s plantation, A. MITCHELL (Dept. Int. Canada, Forestry Branch Bul. 10, 1910, pp. 23, figs. 13).—A bulletin of poplar information prepared to assist farmers in arranging their forest plantations to the best advantage and in bringing them to a successful issue. The following phases are discussed in detail: Narrow v. broad belts, arrangement of plantations, home plantations,
preparation for planting, planting the trees, care of plantations after planting, distances between trees, pruning, thinning, the use of willow and poplar cuttings, gaps in plantations, transplanting, and grading up poplar bluffs.

Wide belts are considered better than narrow ones since they afford better shelter, are cheaper to maintain, and furnish better as well as more material in after years.

Tree planting on the prairies of Manitoba, Saskatchewan, and Alberta, N. M. Ross (Dept. Int. Canada, Forestry Branch Bul. 1, 1910, pp. 104, pIs. 34, figs. 2).—This bulletin has been prepared with the idea of furnishing practical information to the settler on the western prairies as to the best methods of propagating, planting, and managing hardy trees for shelter belts, windbreaks, and plantations. The information is based upon the successful results of planting and general nursery work. Only such trees as have been proved absolutely hardy are recommended for planting.

Part 1 discusses the natural conditions and the benefits to be derived from tree planting on the prairies, and gives directions for establishing plantations. Part 2 contains information relative to the character, uses, cultural requirements, and methods of propagating the various deciduous and coniferous trees recommended.

The Olympic National Forest: Its resources and their management, F. Burns (U. S. Dept. Agr., Forest Serv. Bul. 89, pp. 20, pls. 3).—This bulletin contains an account of the Olympic National Forest in the State of Washington relative to its resources, topography and drainage, land classification, water and agriculture, water power, timber, burns, grazing, mining, settlement, and permanent improvements.

The merchantable stand within this forest approximates 25,500,000,000 ft. b. m. It was established to provide a permanent supply which could be drawn upon when the immense stands now upon private holdings have been cut away. It is estimated that the forest is capable of producing a sustained annual yield of 250,000,000 ft. b. m.

Forest products of Canada, 1909.—Pulp wood, H. R. MacMillan (Dept. Int. Canada, Forestry Branch Bul. 12, 1910, pp. 9).—The pulp wood consumption in Canada is shown by species, Provinces, and processes. There were produced in Canada in 1909, 1,537,762 cords of pulp wood, valued at $9,216,730; 622,129 cords being manufactured there into pulp and 915,633 cords being exported in the raw state.

Forest products of Canada, 1909.—Poles purchased, H. R. MacMillan (Dept. Int. Canada, Forestry Branch Bul. 13, 1911, p. 7).—A statistical review based upon data received from the telegraph, telephone, electric light and power companies, and the electric and steam railroads operating in Canada. The number, total cost, and average cost are given by species, chief uses, and length classes, including comparative data for 1908. The prices of cedar poles in the United States and Canada in 1908 are also compared.

The total number of poles purchased in Canada in 1909 was 358,255, or 92.9 per cent more than in 1908. Cedar is the wood most frequently used, since it is cheap, easily handled, and durable.

Forest products of Canada, 1909.—Cross-ties purchased, H. R. MacMillan (Dept. Int. Canada, Forestry Branch Bul. 14, 1911, p. 8).—A statistical review for the year based upon data furnished by the steam and electric railways of Canada.
There were 14,178,241 cross-ties, costing $5,210,490, purchased by the above railways in 1909. The number and cost of cross-ties are shown by species.

Comparative data relative to the service and cost of treated and untreated ties of common Canadian woods show an annual saving in using treated ties of from 0.2 ct. per tie with cedar to 2.35 cts. per tie where jack pine is used. For the same 2 species the annual saving per mile of track is estimated at $6 and $70.50 respectively.

The total value of tight and slack cooperage stock manufactured in Canada in 1909 amounted to $1,842,235, of which 83.6 per cent represented the value of the slack cooperage stock. Lumber for boxes and shooks was consumed to the value of $1,264,376.

Forest fires and railways, R. H. Campell (Dept. Int. Canada, Forestry Branch Bul. 16, 1911, pp. 8, figs. 2).—This bulletin considers the relation of the railways to forest fires in Canada. The phases discussed include fires arising from railway construction, fires arising from clearing right of way, locomotive equipment, damages, and penalties.

**DISEASES OF PLANTS.**

Investigations on the dissemination of microscopic spores in the atmosphere, G. Bonnier (Bull. Soc. Nat. Agr. France, 71 (1911), No. 3, pp. 292–302, figs. 2).—In addition to giving the results previously reported from another source (E. S. R., 25, p. 143) under this title, the author discusses the influence of rain on the number of spores in the atmosphere of a given locality. It was found that immediately after a rain fewer spores were present in the air, as determined on a given culture medium, than before the rain.

Report of the mycologist for the year ending March 31, 1911, I, J. B. Rober (Bd. Agr. Trinidad Circ. 2, 1911, pp. 1–5).—This report deals with the administrative work and briefly notes the work done along mycological and pathological lines during the past year.

Report on plant diseases for the year 1908–9, R. Schander (Ber. Pflanzenkrank, Abt. Pflanzenkrank, Kaiser Wilhelm's Inst. Landw. Bromberg, 1908–9, pp. 161, figs. 18).—The distribution, prevalence, severity, and method of control of diseases of field, forest, orchard, and garden crops are discussed.

In the first part of the report the general conditions of various crops of the year are taken up. In the second part special reports are made on the pests (fungus, insect, and weed) of each crop in detail, and the results of experiments for their control are noted.

Special attention was given to the heart or dry rot of beets, the potato leafroll disease, and blakleg of the potato (E. S. R., 23, p. 348, 745; 24, p. 46). The effect of different soils, fertilizers, and table salt on the heart or dry rot of beets is given. In studying the leaf-roll disease the amount of diseased and sound plants of several varieties of potatoes was obtained by using, first, several sound seed tubers, and, second, diseased tubers for seed. The relative resistance and susceptibility of many varieties of potatoes is also noted. Blackleg of the potato was widespread during this year, and was often mistaken for the leaf-roll disease.

On the distribution of fungus diseases of plants in Russia during 1908, A. A. Iachevskim (Ezheg. Dept. Zeml. [Russia], 29 (1908), pp. 678–698).—The prevalence of the common diseases of field, forest, orchard, and garden crops, and the damage done by them are noted.
On the distribution of fungus diseases of plants in Russia during 1909, A. A. IACHEVSKIM (Ezheg. Dept. Zeml. [Russia]), 30 (1909), pp. 573–601, pls. 2, fig. 1. — The distribution is given of the common diseases of field, forest, orchard, and garden crops.

Root diseases caused by Armillaria mellea, W. H. LAWRENCE (Better Fruit, 5 (1911), No. 10, pp. 41–44, figs. 5). — The author figures and describes the characteristics of the fungus, and gives its prevalence and the damage done by it in the Puget Sound country. It was found infesting and killing the apple, plum, cherry, gooseberry, prune, currant, blackberry, raspberry, and loganberry.

Fungus diseases of ground nuts in the West Indies, F. W. SOUTH (West Indian Bul., 11 (1911), No. 3, pp. 157–160). — The author describes 3 fungus diseases of ground nuts, 2 attacking the leaves, viz. Uredo arachidis and Cercospora personata, and an unidentified root fungus.

The rust fungus (U. arachidis) is of general distribution, both on local and imported varieties, and the damage done by it varies on the different islands. On some of the islands spraying with Bordeaux mixture was said to be effective in checking the rust, while on other islands neither Bordeaux mixture nor the application of a lime-sulphur mixture appreciably checked the disease.

The root disease occurs on the ground nuts in Barbados, Granada, Dominica, St. Kitts, and Nevis. Attacked plants wilt rapidly and in 2 days from the first wilting of the leaves are completely dead. The fungus kills the roots and then spreads to the collar, base of the stem, and the surface of the nuts, but does not appear to penetrate the nuts themselves, since diseased nuts when disinfected with corrosive sublimate solution produce healthy plants. The fungus when young forms a cobweb-like covering over the diseased portions. The hyphae are colorless and provided with occasional clamp connections. As they grow older, yellow to brown filaments arise in a characteristic manner. No fructifications have been found, but numerous spherical, smooth, brown sclerotia 1 mm. in diameter frequently occur.

The fungus has been found attacking Aroids, Antirrhinums, some Compositeae, eggplants, tomatoes, seedling lime trees, and alfalfa. No certain remedy is known for successfully disinfecting the ground when it is once thoroughly infected, but liming the soil and permitting it to lie fallow for several months is suggested as a possible remedy. Immersion for 5 minutes in 1:1,000 corrosive sublimate is advised for disinfecting the diseased nuts intended for seed.

Rice disease caused by Ustilaginoidea graminicola, E. ESSED (Ann. Bot. [London], 25 (1911), No. 98, pp. 367, 368, pl. 1). — This disease first appears on the rice leaves and sometimes on the sheaths as dark brown, intercostal spots with yellowish margins. A species of Panicum is also attacked by the same organism.

An examination of the diseased areas showed the presence of a fungus, for which the name of U. graminicola is proposed.

Spongospora subterranea, T. G. B. OSBORN (Ann. Bot. [London], 25 (1911), No. 98, pp. 327–341, pl. 1). — The author gives in detail the results of his investigations, a preliminary account of which has been previously noted (E. S. R., 24, p. 742), of the life cycle of this potato scab, including cytological studies of its vegetative and reproductive phases and its effects upon the host plant.

It is claimed that Spongospora belongs to the Plasmodiophoraceae, which group has many points of relationship to the Mycetozoa, differing chiefly in the parasitic habit, in the method of division of the vegetative nuclei, and in the less constant presence of the flagellum on spore germination.

Oospires of potato blight, G. P. CLINTON (Science, n. ser., 33 (1911), No. 854, pp. 744–747). — The author claims to have produced perfect oogonia, anthe-
ridia, and oospores of Phytophthora infestans from pure cultures of the organism grown on a special culture medium.

The oogonia are thick-walled with a more or less roughened or ornamental external coat, and tinted more or less a chestnut brown, while the oospores are moderately thick-walled, smooth, and colorless.

It is also claimed that crosses between P. infestans and P. phascoli, and between P. infestans and P. cactorum, have been obtained by growing mixed cultures of these organisms. The crosses produced oospores, some of which resembled the P. infestans type and others the P. phascoli or P. cactorum type. However, none of the oospores germinated.

A history of the damping-off disease of sugar beet seedlings, A. Stift (Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 40 (1911), No. 2, pp. 211–251).—The author briefly reviews the opinions of prominent investigators as published during the past 10 years on the probable causes of this disease and methods used for its control.

On the history of the heart or dry rot of the sugar beet, A. Stift (Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 40 (1911), No. 2, pp. 252–273).—A brief summary is given of the views of prominent investigators as published during recent years on the cause of this disease, the effects of various fertilizers on it, and methods for its control.

[A fungus disease of the avocado], J. E. Higgins (Hawaii Sta. Rpt. 1910, p. 27).—Attention is called to a fungus disease of avocados, probably caused by a species of Gleosporium, which is prevalent in many parts of the Territory of Hawaii and causes much damage. It turns the attacked leaves a rusty, brown color, and frequently causes them to fall prematurely. It also causes a dying back of the twigs and branches which often terminates in the total destruction of the tree. Flowers were sometimes attacked, the disease extending into the new wood.

Preliminary tests are being carried out with 4 fungicides, viz, 6:6:50 Bordeaux mixture plus arsenate of lead, a resin-lime mixture consisting of 2 gal. of resin lime to 48 gal. of dilute Bordeaux mixture, a 6:6:50 self-boiled lime-sulphur mixture with arsenate of lead, and a 1:50 commercial lime-sulphur mixture with arsenate of lead.

So far none of the sprays have produced any serious foliage injury, but it is yet too early to judge of the fungicidal results.

The Panama disease, I, II, E. Essed (Ann. Bot. [London], 25 (1911), No. 98, pp. 333–361, pls. 2).—A study is reported of the characteristics and cause of this banana disease. It is claimed that a species of fungus belonging to the Hypocreaceae, and for which the name Ustilaginoideella musaperta is proposed, is its true cause.

The author claims to have isolated the fungus, and descriptions are given of various spore forms, sclerotia, conidia, several kinds of chlamydospores, mycececidia, etc. Two species of bacteria (Micrococcus sulfureus and Bacterium fluorescens) were found associated with the fungus.

In the second paper the author gives the results of further studies on the organism and of inoculating experiments with the organism and with the 2 associated bacteria. The so-called sclerotium noted in the first paper is here called pegmatium, and is defined as a structure which arises from well-nourished hyphae and hardens into gristly or gummy bodies having the power to regenerate the fungus by means of chlamydospores or by mycelia arising from them without the interposition of a spore stage.

The reproductive organs are given as ascospores (none of which have yet been found), conidia, chlamydospores, and oidia. Two enzymes were found to be secreted by the fungus, one, probably cytase, capable of dissolving the cell
walls of the host, and the other a proteolytic enzym. The hyphal walls of the fungus were found to be composed almost entirely of chitin. Inoculation experiments with pure cultures of the fungus and of the 2 associated bacteria gave positive results as to the parasitic nature of the fungus, but negative results with the 2 bacteria.

The author therefore claims that U. musarperda is the cause of the Panama disease of bananas as it occurs in Surinam.

The Surinam disease; a condition of elephantiasis of the banana caused by Ustilaginoidella edipigera, E. Essed (Ann. Bot. [London], 25 (1911), No. 98, pp. 363-365, pl. 1).—It is claimed that "big foot" disease of the banana, or elephantiasis, is caused by a fungus for which the name U. edipigera is proposed.

This organism is said to be closely related to the Panama disease fungus, U. musarperda, but differs slightly in some of its reproductive bodies. The fungus first attacks the parenchyma and prosenchymous cells of the peripheral upper region of the rhizome, and the initial infection probably occurs just below the base of the outermost leaves.

The disease is not a serious one, does not spread rapidly, and is easily kept in check by the use of copper-sulphate solutions.

Diseases of the fig tree and fruit, C. W. Edgeerton (Louisiana Stats. Bul. 126, pp. 20, pls. 8).—The author gives the life history, symptoms, distribution, damage done by them, and methods of control of the following diseases of the fig tree in Louisiana: Fig anthracnose (Glomerella fructigena), fig canker (Tubercularia fici), limb blight (Corticium lactum), soft rot of the fig (Rhizopus nigricans), fig rust (Uredo fici), leaf spot (Cercospora sp.), die-back of the twigs, and nematode root galls.

It is claimed that the fungus causing fig anthracnose is the same organism (G. fructigena) that causes bitter rot of apples. It has been known on the fig for at least 5 years in Louisiana, and is characterized by definite localized sunken lesions, or by a general rot of the whole fruit very similar to the lesions on apples due to bitter rot. Cross inoculations were made with this fungus and other anthracnoses from Melilotus indica, cotton, silver maple, apple, pepper, Populus deltoides, clover, and beans. Perfectly typical lesions of the bitter rot appeared on the apple, fig, pepper, and maple, while no infection was produced on cotton, clover, Melilotus, and beans. Other experiments were also tried, using both apples and figs and the apple and fig anthracnoses, and in all cases the results with the 2 forms were identical.

Tests made during the year as to the varietal resistance of different types of figs against anthracnose showed that the varieties could be grouped under 3 heads, viz, (1) those quite severely affected, such as Madeleine and New French, (2) those less severely affected, such as Drop d'Or, Honche de Bray, and Osborne Prolific, and (3) those affected very little or not at all, such as Mission, Brunswick, Reine Blanche, White Ischia, De Constantine, and Celeste. The use of resistant varieties is recommended as the most practical means of controlling this disease, but if susceptible varieties are already planted, the removal of all fig mummies in the fall and the careful pruning of all dead limbs and twigs is suggested as the best means of holding the disease in check.

Fig canker and limb blight have been previously noted from another source (E. S. R., 24, p. 747). The soft rot of the fig may occur to some extent in any season, but is especially severe during wet periods, when often as much as $\frac{3}{4}$ of the figs on a tree will be destroyed by this disease. It is disseminated by wind-blown spores, by insects, especially the Argentine ant, by juice from a diseased fig dropping to other portions of the tree, and by rains washing the
spores off on other parts. The remedies advised are frequent picking of the ripe figs, keeping the ants out of the trees by means of ant tape, etc., and by planting varieties not readily susceptible to the disease, such as Celeste and Reine Blanche.

The fig rust is a very common disease, and usually defoliates the trees in the late summer. No treatment for it is known. Leaf spot and die-back are of little economic importance so far, while the root galls due to nematodes are often quite troublesome in sandy soils but of little importance in sticky, clayey soils. A 3-year rotation with other crops is said to control this disease.

A bibliography is appended.

The American gooseberry mildew order of 1909, T. H. Middleton (Ed. Agr. and Fisheries [London], Intcl. Div., Ann. Rpt. Proc. 1909–10, pp. 73–76).—This order in regard to the control of the American gooseberry mildew is printed in full. It includes directions as to notification of the disease, investigations and action by local authorities, precautions to be observed against the spread of the disease, a prohibition of the importation of the bushes, the powers of boards and inspectors, and penalties under the act.

The influence of the stock on the susceptibility of the graft to grape mildew, L. Ravaz (Prog. Agr. et Vit. (Ed. l’Est-Centre), 32 (1911), No. 19, pp. 598–600).—The author claims that in grapes where the union between scion and stock is perfect, resulting in a vigorous, succulent growth, the susceptibility is increased, while the reverse is true of unions in which there is not a perfect affinity between scion and stock, resulting in a less vigorous and therefore less watery condition of the foliage and young shoots.

The method of the action of sulphur used in combatting powdery mildew, R. Marcille (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 12, pp. 780–783).—The author claims that experiments have not been carefully conducted in determining the manner in which sulphur acts as a fungicide, and he has carried on some experiments in Tunis to settle this point.

It has generally been asserted that the sulphur acts through its volatilization or oxidation, but the author found that under the conditions of his experiments these two functions were of very little importance. He claims that sulphur used for the prevention of powdery mildew owes its efficiency to the sulphuric acid which it contains. Pure sublimed sulphur was found to contain from 0.2 to 0.625 per cent anhydrous sulphuric acid. The sulphuric acid which the sulphur contains under ordinary conditions does not injure the tissues of the plant, but when, through condensation of humidity, the conditions favor the development of mildew, the small drops which form dissolve the acid and impregnate the spores and mycelium of the fungus, which are killed through the concentration of the acid due to evaporation of the solution.

This hypothesis, it is said, explains particularly the efficiency of the extra sublimed sulphurs, as they contain notable quantities of sulphuric acid, while the ordinary and triturated forms of sulphur contain it in very small amount.

The author thinks that for use as a fungicide sulphur should be prepared in such a way as to contain a greater amount of sulphuric acid than that which is ordinarily furnished.

The black-rot disease of grapes, D. Reddick (New York Cornell Sta. Bul. 293, pp. 289–364, pls. 5, figs. 16).—This is a comprehensive discussion of the black rot of grapes, based in part on original investigations by the author, including a history of the disease, the geographical distribution, economic importance, symptoms, name and life history of the parasite, and the meteorological relations, incubation period, period of susceptibility, longevity of pycnospores, pathological histology of the leaf, stem, and berry, and the methods used for controlling this disease.
A bibliography of the disease, consisting of some 350 titles, is appended.

The infection of the grape with *Plasmopara viticola*, H. Müller-Thurgau (Centbl. Bakgr. [etc.], 2. Abt., 29 (1911), No. 23–25, pp. 683–695, fig. 1).—The results are given of inoculation experiments with the conidia of *P. viticola* on the upper and lower leaf surfaces. In every instance no infection was obtained from inoculating the upper surfaces, while inoculations similar as to time, inoculating material, etc., made on the under side of the leaves were very often successful.

In the small dead areas on the older grape leaves large numbers of oospores were found.

**The summer spraying of peaches, J. P. Stewart (Proc. State Hort. Assoc. Penn., 52 (1911), pp. 181–195, figs. 3; Proc. Amer. Pomol. Soc., 32 (1911), pp. 281–292, pls. 2).—**The results are given of experiments with various fungicides as summer sprays for peach orchards, in which the author notes the meteorological conditions during the experimental period, and the effects of the various sprays on the fruit, foliage, twigs, currulio, scab, brown rot, the carrying quality of the peaches, and on the yield, soundness, and color of the fruit.

The sprays used were as follows: Self-boiled lime-sulphur, S: S: 50, plus 2 lbs. of arsenate of lead; lime-sulphur solution, specific gravity 1.003, plus 2 lbs. of arsenate of lead; lime-sulphur solution, specific gravity 1.003, plus 2 pts. of arsenite of lime solution; lime-sulphur solution, specific gravity 1.003, plus 2 lbs. of arsenate of lead, applied with a carbon dioxide gas sprayer; Sulfocide, 1:400, plus 2 pts. of arsenite of lime solution; Sulfocide, 1:400, plus 2 lbs. of arsenate of lead; Pyroxy. 5:50; Bordeaux mixture, ½:6:50 and 4:6:50, plus 2 lbs. of arsenate of lead. The amount of the arsenicals given in each of the above sprays was added to every 50 gal. of the mixture.

A summary of the spray injuries due to compounds of sulphur and arsenic which developed from the experiments undertaken shows that (1) when used in the proper dilutions most of the injury is due directly to the arsenical but indirectly to the solvent action of the fungicide used with it, (2) that arsenicals containing soda are unsafe with certain lime-sulphur sprays, (3) that the use of spray water containing appreciable quantities of sodium salts or the use of commercial lime-sulphurs to which sodium or potash salts have been added is especially dangerous in connection with arsenicals, and (4) that to avoid lime-sulphur-arsenical spray injury, so far as it depends on the materials themselves, it is necessary to eliminate the solvent action of the fungicide by putting it out of solution, coupling this with the use of an arsenical of the highest grade.

It was found that the fungicidal properties of the lime-sulphur spray were not lost by the precipitation of the sulphur when the spray was applied with the gas sprayer. In the control of currulio the arsenatic of lead was not very effective while the arsenate of lime was remarkably so.

Incidentally, the author notes the practical control of currulio on apple trees, even when the first application of the arsenicals was from 10 to 15 days after the petals had fallen and the second some 33 weeks later.

All of the sprays except one (Sulfocide plus arsenate) increased the yields, and all gave a greater percentage of sound fruit than the unsprayed trees, ranging from as low as 53.1 per cent of sound fruit for the Sulfocide and arsenate sprays to 73.9 per cent for the ½:6:50 Bordeaux mixture as compared with an average on the 2 checks of about 10 per cent of sound fruit, while the lime-sulphur and arsenate mixture applied with the carbon-dioxid gas sprayer gave 73.6 per cent of sound fruit. The effects of the spray on scab and brown rot varied considerably, ranging from 22.8 per cent of scab for the Sulfocide and arsenite to 6.57 per cent for the self-boiled lime sulphur and arsenate.
and 5.3 per cent for Pyrox, and from 21.7 per cent of rot for the lime-sulphur and arsenate to 7.2 per cent for the $\frac{1}{2}$:6:50 Bordeaux mixture and arsenate spray as compared with an average of 33.6 per cent of rotted fruit on the check plots.

**Bitter plums**, P. Sorauer (Ztschr. Pflanzenkrank., 21 (1911), No. 3, pp. 145, 156).—Attention is called to the presence of a fungus, *Cephalothecium roseum*, on ripe plums which were offered for sale in the markets of Germany. The affected plums were bitter and had small white spots over their surfaces, from which after about 2 weeks the fruit bodies of the fungus developed.

A thread blight on *Para* rubber, camphor, etc., K. Bancroft (Agr. Bul. Straits and Fed. Malay States, 10 (1911), No. 4, pp. 110–114, pl. 1).—Attention is called to the recent appearance on *Para* rubber and camphor trees (*Cinnamomum camphora*) of a disease called thread blight, due to a fungus which apparently belongs to either the genus *Hypochoniasis* or the genus *Corticium*.

The leaves of the attacked trees wither and hang down, often becoming matted into dense masses. The young twigs also wither, the buds die, and finally the leaves are shed. White rhizomorphic strands are found on the affected branches and spread from them to the under sides of the leaves, where they repeatedly branch until the entire under surface of the leaf is covered with a white mass of fine fibrils. No spore-bearing structures have been found, and the fungus is disseminated by infested leaves being blown to other trees where they adhere to the branches or twigs by means of the dense mycelial growth.

The remedies suggested are the collection and burning of all fallen leaves and twigs from diseased trees.

A disease of seedlings of *Palaquium oblongifolium*, K. Bancroft (Agr. Bul. Straits and Fed. Malay States, 10 (1911), No. 4, pp. 108–110).—The author describes as new *Laestadia palaquii*, a fungus which produces brown spots on the leaves of seedlings of *P. oblongifolium*. These spots increase in size until they often become confluent over nearly the entire area of the leaf, while the remaining portion of the leaf becomes yellow. The leaf finally withers and dies, followed by the withering of the young part of the stem, and eventually by the death of the seedling. A description of the fungus is appended.

A root gall of begonias, K. Schechner (Österr. Gart. Ztg., 6 (1911), No. 5, pp. 161–167, figs. 4).—A description is given of a root gall of this ornamental plant when grown under glass, due, it is claimed, to attacks of the nematode, *Heterodera radicicola*.

**Report of the department of botany**, C. Brooks (New Hampshire Sta. Bul. 151, pp. 21–23).—Self-boiled, home-boiled, and commercial lime-sulphur mixtures as fungicides have been tested both alone and in combination with the various insecticides. The lime-sulphur sprays produced no injury to apple trees and controlled the diseases during 1908 and 1909, but experiments made in 1910 indicate that more frequent applications of lime-sulphur mixtures will have to be made than of Bordeaux mixture during rainy seasons, as the sulphur mixtures wash off the trees more readily than the copper sprays. Arsenate of lead and arsenide of lime when combined with lime sulphur gave no injury, while Paris green when used with commercial lime-sulphur produced slight injuries if there was no excess of lime present (E. S. R., 22, p. 747).

Special attention has also been given to leaf spot of apple, apple scab, fruit spot of apple, and tomato diseases.

Recent advances in our knowledge of lime-sulphur, J. P. Stewart (Proc. State Hort. Assoc. Penn., 52 (1911), pp. 176–181, figs. 2).—A brief review is given of the development of lime-sulphur as an insecticide and fungicide for orchards from its inception on the Pacific Coast to its present prominent
position as a scalecide and fungicide. Special attention is given to the work done in recent years by the Pennsylvania Station in determining that the proper ratio of lime to sulphur for concentrated lime-sulphur mixtures is not constant but varies primarily with the increase in density; that for orchard conditions the best ratio of ingredients is 1 lb. of high grade calcium lime to 2 lbs. of sulphur; that the sedimentation of concentrated lime-sulphur in storage is due to exposure to the air, and therefore easily remedied by keeping in completely filled air-tight vessels; and that the inauguration of a definite system of dilution in the use of lime-sulphur sprays is advisable.

Notes on a modified soda-Bordeaux mixture, V. Vermorel and E. Dantony (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 14, pp. 972–974).—The authors describe 2 copper-soda sprays, to which soap was added to increase their adhesive or wetting power.

It was found that when 2 kg. of copper sulphate dissolved in 50 liters of water and 2 kg. of carbonate of soda in 50 liters of water were mixed by pouring all of the carbonate of soda solution immediately into the sulphate solution a precipitate was formed without the liberation of carbon dioxid. The resulting mixture finally contained insoluble hydrocarbonate of copper and soluble bicarbonate of copper, which the authors call mixture A. If the carbonate of soda is gradually and slowly poured into the sulphate of copper solution, carbon dioxid is evolved and the mixture finally contains insoluble hydrocarbonate of copper and an excess of carbonate of soda; this is called mixture B.

If to mixture A 1,000 gm. of white soap free from carbonate and alkalis and very rich in oleate of soda is added, the superficial tension of the mixture is such that 5 cc. forms 85 drops as compared to 66 drops formed from 5 cc. of distilled water used as a standard, and this tension does not vary with time. If to mixture B only 100 gm. of the soap is added the mixture will have a superficial tension of 85 drops the same as mixture A, but the tension in B so decreases that at the end of 3 hours it has only 83 drops. When 1,000 gm. of the soap is added to mixture B the tension will be 151 drops immediately after the addition of the soap, 139 drops 20 minutes after, 125 drops 1 hour after, 113 drops 3 hours after, 100 drops 6 hours after, and so on until it reaches the 85 drop limit of mixture A. This increase in the number of droplets increases the wetting power of the spray, and differs according to the manner of the preparation of mixtures A and B and the subsequent action of their superficial tension when the soap is added. This explains, so it is claimed, the divergence of opinion of different investigators as to the value of such sprays.

On the use of Schweinfurt Paris green for controlling plant diseases, T. S. Hofman (Verslag. Landbouweck. Onderzock. Rijkslandbouwproefstat. [Netherlands], 1911, No. 9, pp. 26–35).—On account of a serious foliage injury which occurred to fruit trees from the use of this substance on certain orchards the author investigated the causes of this injury, and reports the results of his investigations.

From microscopical and chemical tests of the Paris green the conclusion is reached that the injury was probably due to the use of spray water containing ammonia or ammonium carbonate which rendered soluble appreciable quantities of the arsenic. It was also found that the copper present in the Paris green was inert and quickly changed to cuprous oxid.

**ECONOMIC ZOOLOGY—ENTOMOLOGY.**

Atlas of zoogeography, J. G. Bartholomew, W. E. Clarke, and P. H. Grimshaw ([Edinburgh], 1911, pp. 67–XI, pls. 36, figs. 2).—The object of this atlas is to delineate and describe, so far as the state of our knowledge permits, the
present distribution of the higher animals over the surface of the earth. This undertaking is stated to be based upon the result of original researches into the zoological literature of all countries. All the families of mammals, birds, reptiles, and amphibians, together with several of the more important genera and species, have been dealt with, and in addition most of the families of fishes and a selection of families and genera of molluscs and insects.

The text is divided into 5 parts. In part 1 (pp. 1–3) a short historical account is given of the various systems propounded for the subdivision of the world in zoogeographical regions, wherein the views of the leading authorities are considered; in part 2 (pp. 4–12) the various regions and subregions of Wallace are defined and an account given of their characteristic and peculiar animals, with original tables, giving a numerical summary of the families of terrestrial vertebrates occurring in these areas; part 3 (pp. 13–56), the main portion of the text, is designed to afford concise information regarding the groups of animals the distribution of which is shown on the plates. A census based upon the latest information is given where possible of the number of known species of each family. In part 4 (pp. 57–67) a bibliography is given which contains a list limited to about 1,000 titles of the more important books and papers dealing with the animals of the various regions. The titles are arranged alphabetically under the authors' names, and are then grouped primarily under the regions, and secondarily under the various classes of animals.

The 36 plates embrace a series of 200 colored maps which illustrate the distribution of over 700 families, genera, and species of existing animals. A full and comprehensive index is appended.

The mammals of the tenth edition of Linnaeus; an attempt to fix the types of the genera and the exact bases and localities of the species, O. Thomas (Proc. Zool. Soc. London, 1911, 1, pp. 120–158).—The author states that in preparing this paper Linnaeus's quotations have been verified through reference to the original works.

On the common shrew mole (Scalopus aquaticus machrinus) in Illinois, F. E. Wood (Bul. Ill. State Lab. Nat. Hist., 9 (1910), Art. 1, pp. 1–13, figs. 2).—Anatomical and bionomic studies of the species of shrew mole that occurs in most of Illinois and throughout the eastern half of the United States are presented.

Collections made from different parts of the State indicate a gradual increase in size from east to west, across the State. The investigations indicate but 1 litter a year, which is brought forth the latter part of April or early in May.

In Illinois the chief complaint against moles has been that they destroy recently-planted corn, in some cases it being said that 25 per cent of the first planting has been destroyed. The author finds that moles work in corn fields all summer and fall but the damage is practically all done within the first 10 days after planting. Experiments conducted during the season of 1908 with repellents in which seed corn was treated with kerosene, carbolic acid, formalin, oil of lemon, and other vegetable oils, failed to give definite results, except in cases where the quantity used was so great as to injure the seed.

Studies upon plague in ground squirrels, G. W. McCoy (Pub. Health and Mar. Hosp. Serv. U. S., Pub. Health Bul. 43, 1911, pp. 7–51).—These studies are reported in 4 parts under the headings, (1) pathology and bacteriology of plague in ground squirrels, (2) notes on induced plague in ground squirrels, (3) immunity of certain squirrels to plague infection, and (4) insect transmission in relation to plague among ground squirrels.

Food of the woodpeckers of the United States, F. E. L. Beal (U. S. Dept. Agr., Bur. Biol. Survey Bul. 37, pp. 64, pls. 6, figs. 3).—This bulletin describes
the food habits of 16 important species of woodpeckers, and points out the extent to which each is beneficial or injurious. While most woodpeckers are highly beneficial, the sapsuckers are injurious, since they subsist to a considerable extent on the cambium or inner bark of trees.

Index-catalogue of medical and veterinary zoology, C. W. Stiles and A. Hassall (U. S. Dept. Agr., Bul. Anim. Indus., 39, pl. 32, pp. IV+2583-2654).—This part lists the literature by authors from Werlhof to Xémard.

Forty-first annual report of the Entomological Society of Ontario, 1910 (Ann. Rpt. Ent. Soc. Ontario, 41 (1910), pp. 124, pls. 3, figs. 23).—Among the papers of economic importance presented in this report are accounts of the occurrence of insects during the year, by A. Gibson, L. Caesar, C. G. Hewitt, T. W. Fyles, and others; the seed corn or bean maggot (Pegomyia fusciceps) in Ontario in 1910, by J. E. Howitt; the horse-radish flea beetle (Phyllotreta armoraciae), by A. F. Winn; the migration of some native locusts, by X. Criddle; some observations on the practical importance of the study of parasitic insects, by C. G. Hewitt; the Cocciidae of Canada and the Aleyrodidae of Ontario, by T. D. Jarvis; some insects of the larch and insect notes from St. Anne's, by J. M. Swaine; and basswood or linden insects, by A. Gibson.

On one plantation pineapple plants were badly damaged in the fall by an introduced locustid (Xiphidium variipenne) which attacked the leaves, making large abrasions that permitted the entrance of fungi and caused the leaves to wilt and die back. The eggs of this locustid are highly parasitized, however, and it is not likely to become a serious pest. The edible nuts of the litchi tree in several Honolulu gardens were badly attacked in July by a tortricid moth (Cryptophlebia illepida), the larvae of which bore into the succulent fruit and render it unfit for use. In one orchard the entire crop was destroyed.

A brief report is made on introductions of parasites of the algaroba weevil in cooperation with the Bureau of Entomology of this Department. Lists are given of the insects that attacked corn, wheat, barley, jack bean, and cotton.

Report of the department of entomology, W. C. O'Kane (New Hampshire Sta. Bul. 151, pp. 39-46).—This is a report of the department for the biennial period ended October 30, 1910.

One of the principal investigations was that of the apple maggot or railroad worm, of which a brief summary of the results obtained to date is here presented. The author states that 95 per cent of the orchards of the State were found to be more or less infested by this pest. Seventy-one varieties have thus far been studied to determine their susceptibility to attack, and certain varieties found especially susceptible, others only occasionally infested, and 1 or 2 varieties practically immune. Studies of apples in cold storage show that as a rule deterioration is more rapid in the case of infested fruit.

The author finds that the first eggs are laid soon after the flies begin to emerge, about July 2 to 5, and that egg-laying continues through July and August, and probably into September. It is stated that this is true regardless of variety, except that the eggs are not laid in early apples after they have ripened and dropped from the tree. It was found that where winter fruit such as the Baldwin becomes infested, the early drops falling in August may easily become sufficiently mellow to permit the maggots to mature. On the other hand badly infested Baldwins gathered early in October failed to mature a single maggot and the same was found to be true of russets. Thus in the case
of winter varieties, it is the early drops that should be disposed of in order to destroy the maggots.

In investigations made to determine how soon after dropping the maggots leave the apples, "it was found that in the case of such varieties as the August Sweet or the Early Harvest some maggots began to emerge within 36 hours, though they did not come out in large numbers until 3 or 4 days had elapsed since the apple fell from the tree. With varieties such as the Gravenstein a week elapsed before the maggots began issuing in any considerable numbers. In the case of winter fruit, such as the Westfield, practically no maggots emerged until after the apples had been off the tree from 2 to 4 weeks." In the case of fall fruit it is thought to be sufficient if the drops are cleaned up twice a week, while with the winter fruit the same results will be obtained by cleaning up once in 2 weeks. The author finds that there is nothing to indicate that the adult flies normally travel any great distance.

Experiments indicate that it is not possible to bury the pupae so deep by plowing that the flies will be unable to reach the surface, thus corroborating the observations made at the Rhode Island Station (E. S. R., 16, p. 794). The author reports that by spraying with sweetened arsenical, practically perfect fruit were obtained from an August Sweet tree which during previous years yielded worthless fruit only.

The author reports that during the season of 1910 there was an almost complete cessation of the abnormal numbers of the antlered maple worm (Heterocampa gattilitta) (E. S. R., 21, p. 759). Specimens were observed at various points but they did not appear in sufficient numbers to cause injury.

Brief notes are also given on experiments in the control of the black fly (E. S. R., 23, p. 359).

Sixth annual report of the state entomologist and plant pathologist for 1910, G. M. Bentley (Bieum. Rpt. Tenn. Dept. Agr., 1909–10, pp. 19–69, pls. 19, fig. 1).—This report includes an account of the periodical cicada (Cicada tredcim) in Tennessee in 1911, notes on the important insects that occurred during the year, the laws and regulations relating to nursery inspection, etc.

[Reports of the entomologist and assistant entomologist], F. W. Urich and P. L. Gypsy (Bd. Agr. Trinidad Circ. 2, 1911, pt. 1, pp. 5–11).—In these brief reports of the work of the year mention is made of the occurrence of sugar-cane, cacao, coconut-palm, and other insects.

Insect pests in 1910, R. S. MacDougall (Trans. Highland and Agr. Soc, Scot., 5, ser., 23 (1911), pp. 117–151).—The author found during the year that the black-blue fly (Protocalliphora granulandica) attacks live sheep and that its maggots, like those of Lucilia sericata and Calliphora cyrthrocephala, are the source of injury to sheep in Scotland. Dermestes vulpinus was found to riddle completely with holes recently placed wooden beams in a guano factory. Notes are also presented on the occurrence of the large larch sawfly (Nematus erichsoni), the raspberry beetle (Byturis tomentosus), and the raspberry moth (Lampronia rubiella).

Some local insects of economic importance, A. F. Navarro (Philippine Agr. and Forster, 1 (1911), No. 2, pp. 32–35).—Notes are presented on a number of insects of economic importance at Los Baños, P. L., namely, the corn-moth borer (Pyrausta vastatrix), the banana leaf roller (Erionota thrax), the ilang-ilang moth (Attacus atlas lorynii), the gabi moth (Charocampa celerio), a nymphalid (Anosia chrysippus), the red cotton bug (Dysdercus cingulatus), the rice army worm (Spodoptera mauritia), a pierid (Catopsila pyranthe), and an aganaid (Asota philippina).

[Control of citrus insects], J. E. Higgins (Hawaii Sta. Rpt. 1910, pp. 35, 36).—The author finds fumigation with hydrocyanic-acid gas to be the most
effective means experimented with in controlling the mealy bug (*Pseudococcus
glomeratus*). Reinfestation takes place more rapidly than in the case of the
Florida red scale (*Chrysomphalus aonidum*) and the purple scale.

[Two insect pests of the avocado], J. E. Higgins (*Hawaii Sta. Rpt. 1910,
p. 26, 27*).—The avocado mealy bug (*Pseudococcus nipar*) and the larva of
the tortricid moth *Amorbia emigratella* were the 2 chief insect pests of avocado
in the station orchard during the year, the latter causing considerable damage
to foliage in the orchard and to the fruit in gardens of the city. Frequent
sprayings with arsenate of lead considerably reduced their numbers.

Five important grape insects and their repression, F. H. Hall (*New York 
State Sta. Bul. 331, popular ed., pp. 3-16, figs. 10*).—A popular edition of
Bulletin 331, previously noted (E. S. R., 24, p. 751).

31*).—The author reports having found it necessary to fumigate trees in the
mango orchard for the destruction of *Pseudoceras eugenica* and for the Florida
red scale (*Chrysomphalus aonidum*). A red-banded thrips (*Heliothrips rubro-
chactus*) caused serious damage to young mango seedlings in the greenhouse, but
was controlled by dusting the plants with finely powdered sulphur after they had
been sprayed with water. *Amorbia emigratella* also proved destructive to
mango flowers and to some degree to the young leaves.

The large carpenter bee (*Xylocopa anaeipennis*) did considerable damage to
young mango buds. "The bee seems to find an inviting place for boring just
above the bud on the bud shield, and in many instances bored through the shield
into the old wood of the stock, causing injury and sometimes destruction to the
bud. It has been found easy to control this injury by placing grafting wax in
all the incisions, leaving only the bud and a small portion of the shield exposed.
This should be done when the bandage is removed, if injury of this kind is
experienced."

Insect enemies of the pecan, F. H. Chittenden (*Nutt Grower*, 10 (1911), 
Nos. 3, pp. 40-43; 4, pp. 61-63, 65, 66, figs. 6).—Some of the more important
insect enemies of the pecan are here considered.

19, pp. 961, 963, figs. 4).—During the course of this account the author states
that in Honduras, because of the screw worm, wild beasts, neglect, and ex-
posure, but 15 per cent of the calves reach maturity. Mention is made of injury
by the so-called cattle spider. "This spider seeks the hair of the fetlock for
lining its nest, and as the beast moves at feeling the removal of the hair, the
spider becomes enraged and bites the flesh just above the hoof on the pastern
and creates an inflamed condition of the skin which results in the loss of the
hoof."

Termite life in Ceylon, K. Escherich (*Termiteleben auf Ceylon. Jena, 
1911, pp. XXXII+262, pls. 3, figs. 68; verr. in Science, v. ser., 33 (1911), No. 849, 
pp. 530-531*).—A monographic study of white ants, based on observations made
during a trip of several months to Ceylon, is presented.

The first chapter (pp. 1-37) is devoted to the nests of the mound-making
termite, including fungus gardens, termiophiles, etc.; the second (pp. 98-134)
to the habits of the species of Eutermes; the third (pp. 135-161) to miscellane-
ous observations and laboratory experiments; and the fourth (pp. 162-179) to
economic considerations.

Extermination measures recommended are (1) the stopping of some of the
main openings of the nest with tow or waste soaked with carbon bisulphid and
closing the remaining openings with clay or earth, and (2) the use of an ant-
exterminator machine. A description is given of a "Termitsucher," an ap-
paratus used in locating the termites. It "consists of a microphone inserted in
a funnel at the end of a steel tube and connected with a telephone receiver. When the tube is stuck into the earth the noise made by the crawling termites can be distinctly heard through the receiver even when they are working at a considerable depth in the soil. By means of this apparatus termites may be readily located in the tree trunks of orchards or estates or in the walls of houses and marked for treatment with the arsenic-sulphur fumes," generated in the exterminator apparatus.

The work closes (pp. 185-252) with a series of appendixes by various authors who have studied the material collected in Ceylon. The review is by W. M. Wheeler.

Studies of Mallophaga and Anoplura, E. Möberg (Ark. Zool., 6 (1910), No. 13, pp. 296, pls. 5, figs. 156).—This work on the morphology and classification of the biting and sucking lice includes descriptions of new genera and species. A host index and bibliography of 14 pages are appended.

Experiments with cotton stainers, W. Ronson (Agr. News [Barbados], 10 (1911), No. 235, p. 138).—"Practically no effect on germination was produced by the feeding of the stainers on seed which had been protected during growth, and exposed to the feeding only after being harvested, while the seed which was produced in bolls attacked during growth showed a very small relative germinating power. . . . The lint was affected to a very serious extent where the stainers were abundant during the development of the cotton."

The white fly (Aleyrodes citri), F. W. Mally (Texas Dept. Agr. Bul., n. ser., 1910, No. 6, pp. 14).—A brief summarized account is given, with directions for the preparation and use of insecticides.

Danger of general spread of the gipsy and brown-tail moths through imported nursery stock, C. L. Marlatt (U. S. Dept. Agr., Farmers' Bul. 453, pp. 22, figs. 7).—This bulletin gives a record of the infested importations of nursery stock during the last 2 years, describes nursery conditions in Europe showing the nature of the infestation there, and concludes with a brief description and illustrations of the 2 moth pests which are now being thus imported. Descriptions and figures are included as an aid to a prompt recognition of the pests.

A new species of Lasioptera with observations on certain homologies, E. F. Felt (Psyche, 18 (1911), No. 2, pp. 81-86).—The gall midge here considered, L. portulacaæ, n. sp., was reared from stem galls on purslane (Portulaca oleracea) at St. Vincent, West Indies.

Some facts about malaria, L. O. Howard (U. S. Dept. Agr., Farmers' Bul. 450, pp. 13, figs. 6).—In this publication, which has been prepared to meet a strong demand for information on the subject by persons connected with agricultural pursuits in various parts of the country, the author considers the nature of the disease, its conveyance by mosquitoes, the mosquitoes concerned, and preventive and curative measures.

Remedies and preventives against mosquitoes, L. O. Howard (U. S. Dept. Agr., Farmers' Bul. 444, pp. 15).—This popular account is largely a condensation of the more important of the matter issued in Bulletin 88 of the Bureau of Entomology, previously noted (E. S. R., 24, p. 458).

Food habits of Megarhinus, F. Knahr (Psyche, 18 (1911), No. 2, pp. 80-82).—The structure of the female proboscis of Megarhinus and personal observations of M. septentrionalis and M. superbus lead the author to conclude that the mosquitoes of this genus feed wholly upon sweets of flowers. While all the parts of the proboscis found in the females of the blood-sucking species are
present in _Megarhinus_, the sheath or labium is strongly chitinized and rigid, which is not the case with the blood-sucking forms.

The _papataci_ flies (Phlebotomus) of the Maltese Islands, R. Newstead (Bul. Ent. Research, 2 (1911), No. 1, pp. 47-78, pls. 3, figs. 19).—In this report of investigations conducted by the author during a 2 months' trip to the Island of Malta, he discusses the habits and occurrence of the adult flies, breeding places, seasonal prevalence, prophylactic measures, etc., also the classification of the genus Phlebotomus. Two species are described as new to science.

Preliminary report on the life histories of 2 species of Syrphidae, C. L. Metcalf (Ohio Nat., 11 (1911), No. 7, pp. 337-344, pls. 2).—Studies on the life history of _Didca fuscipes_ and _Syrphus torvus_ are here reported, together with technical descriptions of the larval, pupal, and adult stages.

"The larva of _D. fuscipes_ live in the colonies of the large aphid, _Longistigma (Lachanus)_ caryae which appear so abundantly in full on the under sides of the lower horizontal branches of the sycamore (_Platanus occidentalis_). I have also found the larva on a basswood tree (_Tilia americana_) affected with these plant lice. They are apparently closely restricted in food habits to the body fluids of this one kind of aphid and may be expected wherever _L. caryae_ occurs with any regularity."

The autumn generation of larva of _S. torvus_ appears on cabbage affected by plant lice, usually during the latter half of September, becoming abundant from the first to the middle of October. The food of the larva usually consists of the body juices of the cabbage plant louse (_Aphis brassicae_). The author has also found the larva of this species on sycamore, feeding on _L. caryae_.

The house fly, disease carrier, L. O. Howard (New York, 1911, pp. XIX+312, pls. 28).—The main part of this work consists of 5 chapters devoted respectively to the zoological position, life history, and habits of the typhoid fly; its natural enemies; the carriage of disease by flies; remedies and preventative measures; and other flies frequenting houses. The work concludes with a bibliographical list of 12 pages and 5 appendixes.

Transmission of tuberculosis by flies, P. Jacob and M. Klofstock (Tuberculosis, 9 (1910), No. 11, pp. 496-510, figs. 2; abs. in Internat. Centbl. Gesam. Tuberkulose Forsch., 5 (1911), No. 3, p. 125).—The authors discuss the relation of flies to the transmission of tuberculosis, particularly from animal to man, in rural districts. As a preventive for this they recommend a thorough disinfection of the barns, stables, etc.

Lucilia sericata as a household pest, A. P. Morse (Psyche, 18 (1911), No. 2, pp. 89-92, fig. 1).—Flies, which developed in a dead squirrel in a chimney, gained entrance through a fireplace and were the source of great annoyance for a period of several weeks.

The parasites of the olive fly in Tunis, P. Marchal (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 9, pp. 213-218, figs. 3).—During the course of studies in Tunis the author found 2 chalcidid (_Eulophus pectinicornis_ and _Eupelmus uroconus_) and a braconid (_Opius concolor_) parasites of the olive fly, _Dacus oleae_. The chalcidid parasites occur in southern Europe but the braconid, which plays an important part in checking the multiplication of the olive fly, is recorded for the first time as a parasite of this pest and is also the first internal parasite of the olive fly to be discovered. Attempts are being made to establish this parasite in Europe.

The destruction of fleas by exposure to the sun, J. Cunningham (Sci. Mem. Med. and Sanit. Depts. India, u. ser., 1911, No. 40, pp. 27, figs. 3).—The experiments here reported have led the author to the following conclusions:

"The pulicidal power of the sun appears to be chiefly due to the amount of heat which it gives off. The fate of the fleas, which escape from clothes ex-
posed to the sun, depends on the nature of the ground upon which the clothes are spread. On hard ground, and more especially on sand, the fleas are all destroyed; on grass they will in all probability be able to find shelter and therefore escape. The time of exposure necessary to destroy all the fleas is about 45 minutes when the clothes are spread on hard ground, and is probably somewhat less when sand is employed."

The experiments show that "the temperatures between 95 and 112° are not strong enough to destroy all the fleas, although there is a great diminution in their numbers in the 2 last experiments which registered 112°. From 116° upwards all the fleas were killed. The minimum temperature, therefore, lies between 112 and 116°, probably 116° itself, because in 2 experiments which were carried out by gradually heating a test tube containing fleas by immersion in warm water, it was found that the exact temperature at which they were killed was 116.4° on the first occasion and 118.4° on the second. If we add 4° to this result, which has been obtained experimentally, and call the minimum 120°, we may be certain of obtaining a temperature which will be fatal under the most practical conditions."

Two species of cysticercoids from the rat flea (Ceratophyllus fasciatus), W. Nicoll and E. A. Minchin (Proc. Zool. Soc. London, 1911, I, pp. 9–13, figs. 2).—Much of the data here presented relating to the occurrence of Hymenolepis diminuta in the rat flea has been previously noted from another source (E. S. R., 25, p. 158).

Experiments in which rats were fed daily with fleas mashed up in their food demonstrate that the complete development of H. diminuta may take place in less than 3 weeks. A single specimen of a second cysticercoid, thought to be H. murina, was met with in the body cavity of a male C. fasciatus.

The mechanism of transmission of Trypanosoma lewisi from rat to rat by the rat flea, C. Strickland (Brit. Med. Jour., 1911, No. 2627, p. 1049).—"Infection of rats with T. lewisi is caused by the rats' act of eating infective fleas. It is not caused by contamination of the rats during a short time, nor by their being bitten by the fleas. Many more fleas are infective than cause infection in nature. The infective form of the trypanosome, which is probably the 'small trypanosome' of Swellengrebel and Strickland, must reach the blood through the gut wall. It is possible that other trypanosomiases may be transmitted by perhaps even nonblood-sucking creatures."

Bees, E. F. Phillips (U. S. Dept. Agr., Farmers' Bul. 447, pp. 48, figs. 25).—This supersedes Farmers' Bulletin 397 (E. S. R., 23, p. 365) and gives briefly such information as is needed by persons engaged in the keeping of bees.

The honey bee in Vermont, H. W. Beecher (Vt. Agr. Bul. 6, 1910, pp. 29, fig. 1).—This bulletin discusses the history of bee keeping and of bee-keepers' organizations in Vermont, the present extent of the industry in the State, wintering, commercial aspects, the value of honey as a food, sources of honey, bee diseases and enemies, etc.

The treatment of bee diseases, E. F. Phillips (U. S. Dept. Agr., Farmers' Bul. 442, pp. 22, figs. 7).—This bulletin supersedes Circular 70 of the Bureau of Entomology, previously noted (E. S. R., 18, p. 561). It gives briefly the information needed by the beekeeper who has disease in his apiary.

Biological notes on Pimella pomorum, Mokrzecki (Ztschr. Wiss. Insektenbiol., 7 (1911), No. 2, pp. 63, 64, figs. 3).—The author reports having found this ichneumon to parasitize as high as 75 per cent of the apple blossom weevils (Anthonomus pomorum) in orchards in Crimea.

Some parasites of Lasius fuliginosus, L. niger, and L. flavus, W. C. Crawley (Ent. Rec. and Jour. Variation, 23 (1911), No. 1, pp. 22, 23).—The occurrence of Antennophorus grandis, as a parasite of aut larvae, is reported. In one nest as high as 12 per cent of the ants were found to be infested by this mite.

A new sawfly of economic importance, S. A. Rohwer (Ent. News, 22 (1911), No. 6, pp. 263-265, figs. 6).—Catirao (Eriocampoides amygdalina) which has been found to defoliate peaches in the vicinity of Tallulah, La., is described as new to science.

Technical papers on miscellaneous forest insects.—IV, Studies in the sawfly genus Hoplocampa, S. A. Rohwer (U. S. Dept. Agr., Bur. Ent. Bul. 20, pl. 4, tech. serv., pp. 139-148, pls. 3, fig. 1).—This second paper on sawflies (E. S. R., 24, p. 662) includes descriptions of 10 new species of Hoplocampa. A synoptic table of the Nearctic species of the subgenus Hoplocampa is included.

An insect injurious to spruce trees, A. H. Cockayne (Jour. New Zeal. Dept. Agr., 2 (1911), No. 3, pp. 117-121, figs. 2).—A species of red spider closely related to Tetanychus bimaculatus is reported to have become the source of considerable injury to various species of Abies, especially A. menziesii, in the South Canterbury district of New Zealand. Infestation is first manifested by a yellowing of the leaves of young branches. The leaves soon become dry and fall off.

A contribution to our knowledge of insecticides, C. T. McClintock, E. M. Houghton, and H. C. Hamilton (Rpt. Mich. Acad. Sci., 10 (1908), pp. 197-208, pl. 1; reprint).—“The work reported in this paper has to do with the contact insecticides only. . . .

“The insecticidal, germicidal, and toxic values (for higher animals) have little or no correlation. It is possible to determine the relative strength or value of insecticides by immersing test insects in definite strengths of the insecticide, and noting the time required to produce death. The common bedbug (Cimex lectularis) appears to be the most satisfactory test insect. As yet the mode of action, the way in which the contact insecticides cause the death of the insects, has not been determined. Apparently the fewer the number of spiracles, the smaller their size, and the better they are guarded by hairs or valves, the more resistant is the insect to the contact insecticides.

“Chemical standardization of this class of insecticides is with our present knowledge impossible. With 2 substances, having essentially the same chemical composition, the insecticidal values may vary enormously. Even the same substance, prepared with what are apparently unimportant chemical variations, gives widely different insecticidal values.”

A further contribution to our knowledge of insecticides, C. T. McClintock, H. C. Hamilton, and F. B. Lowe (Jour. Amer. Pub. Health Assoc., 1 (1911), No. 4, pp. 227-233, pl. 1).—“It is possible to standardize substances which are subject to sophistication or deterioration by comparing the efficient dilution of their vapors with that of a product of known purity. This is particularly applicable to solutions of nicotine and to powdered chrysanthemum flowers. As yet there is nothing from which to conclude what action the vapors have on the insects. If it were merely irritative, formaldehyde would be valuable and the vapors of burning insect powder without value. If the action
were similar to anesthesia, chloroform should have been of greater value. If the action were purely that of poisoning one would have expected the highly poisonous hydrocyanic-acid gas to be of exceptional value for all species of insects."

Hydrocyanic-acid gas fumigation in California.—Fumigation of citrus trees, R. S. Wogium (U. S. Dept. Agr., Bur. Ent. Bul. 90, pt. 1, pp. IX+81, pls. 8, figs. 12).—The author presents a succinct account of the completed results of fumigation investigations with a brief discussion of the salient features of fumigation as practiced in California at the present time. "It is of the nature of a handbook on the most up-to-date equipment, methods, and directions in orchard fumigation. Full advantage has been taken of the results of other investigators in fumigation; yet in such cases due credit is given to the proper source. The information given in Bulletin 79 of this Bureau [E. S. R., 21, p. 354], which is a preliminary report on this investigation, has been largely included in the present bulletin in summarized form."

Hydrocyanic-acid gas fumigation in California.—The value of sodium cyanid for fumigation purposes, R. S. Wogium (U. S. Dept. Agr., Bur. Ent. Bul. 90, pt. 2, pp. 83-90, pls. 2).—This paper records the results secured with sodium cyanid during an investigation of the use of hydrocyanic-acid gas for fumigation of citrus trees in California and is supplementary to the extended report on the use of potassium cyanid above noted. A preliminary account by the author has been previously noted (E. S. R., 23, p. 357).

The author here discusses the proportion of chemicals to use, field tests, the action of sodium chlorid, the kind of cyanid to purchase, dosages with sodium cyanid including charts for field use, dosages recommended for scale pests, and a comparison of sodium cyanid and potassium cyanid for general fumigation.

"From the results of field work in this investigation it has been found that the use of a high grade, or almost chemically pure, sodium cyanid produced exactly as perfect a generation of gas in all cases as the use of a similar grade of potassium cyanid; in the majority of cases where used the generation was apparently superior to that from a potassium cyanid."

A fungicide and insecticide blower, E. Zacharewicz (Prog. Agr. et. Vit. (Ed. l'Est-Centre), 32 (1911), No. 18, pp. 556-559, figs. 6).—The author figures and describes an instrument to be used in applying powdered insecticides and fungicides on a large scale to grain and field crops by means of horse power.

Analysis of Paris green, 1910, J. W. Kellogg (Penn. Dept. Agr. Bul. 204, 1911, pp. 33).—In 416 samples of Paris green analyzed, the arsenious oxid in combination with copper was found to vary from 49.47 per cent to 57.68 per cent, with an average of 55.10 per cent. Only 2 samples were found to contain less than 50 per cent, the required amount of this form of arsenic.

"The amount of water soluble arsenious oxid found present in the samples analyzed varied from 0.72 per cent to 3.45 per cent, with an average of 1.32 per cent. None of the green examined was found to contain water-soluble arsenic in excess of the amount restricted by law. The results obtained in determining the total content of arsenious oxid showed the lowest percentage to be 51.60, the highest percentage to be 61.2, with an average of 56.61 per cent. The amount of copper, expressed as copper oxid, which was determined in the samples received, was found to range from 23.75 per cent to 30.93 per cent, with an average of 29.55 per cent."
The milling value of water-soaked wheat, G. A. Olson (Amer. Food Jour., 6 (1911), No. 4, pp. 36–39, figs. 4).—The effect of soaking and germination on the distribution and yield of milling products, the quality of flour, and bread-making properties was studied.

According to the author's conclusions, "wheat which has been allowed to sprout loses in weight as the length of the time allowed for germination advances.

"The milling value of germinated wheat decreases as the length of the epicotyl increases.

"The length of time required for the conversion of starch decreases as the length of the epicotyl increases to at least twice the length of the kernel."

It was found that the amount of gluten recovered in flour from germinated wheat was less than that from ungerminated grain. The yield of gluten decreased rapidly as the epicotyl increased in length.

"Expressed in percentage of total nitrogen, the alcohol-soluble nitrogen has not been affected by the germination of wheat. The most marked changes were observed in the glutenin and amid nitrogen. In the former there was a sudden decrease in amount from the period where the epicotyl was equal to the length of the kernel to that where the epicotyl was equal to twice the length of the kernel. The amid nitrogen increased rapidly from the time when the epicotyl was equal to the length of the kernel.

"Using germinated wheat flour, only the quality of the crumb of the bread was impaired, being particularly noticeable in flours made from germinated wheat where the epicotyl was equal to and twice the length of the kernel. The volume of the loaf increased, being of exceptionally large capacity in the bread made from partially germinated wheat flour.

"Using small quantities of germinated wheat flour with other flour it was found that the volume of the loaf could be increased without impairing the texture of the loaf. Each particular flour requires a different amount of germinated flour in order to produce the best results. Too large an amount of diastatic flour is less beneficial than none.

"A water-soaked wheat is not necessarily spoiled and can be used for milling purposes, providing it has been thoroughly cleaned and dried.”

On the chemical changes produced in flour by bleaching, G. W. Monier-Williams (Rpts. Local Govt. Bd. [Gl. Brit.], Pub. Health and Med. Subjs., n. scr., 1911, No. 49, pp. 33–65, dysms. 6; rev. in Brit. Med. Jour., 1911, No. 2624, pp. 381, 382).—Experimental studies were made on the effects of bleaching flour with different quantities of nitrous oxalid gas. Special attention was paid to experimental methods, to the characteristics of the oil from bleached and unbleached flour, to the influence of bleaching upon digestion, and related matters. The nitrous oxalid used was prepared in the laboratory.

Air containing nitrogen peroxd in quantities up to 300 cc. per kilogram of flour affects flour in ways which the author summarizes as follows:

"The golden-yellow tint of the flour is destroyed. Immediately after bleaching no difference in tint due to excess of the bleaching agent could be observed with Lovibond's tintometer, but on keeping for several days the more highly bleached samples became decidedly yellow, while those treated with 30 to 100 cc. of nitrogen peroxd per kilogram became still whiter, the maximum of bleaching effect being attained within these limits.

"The amount of nitrous acid or nitrites present in a freshly bleached flour is approximately proportional to the amount of nitrogen peroxd employed, and
corresponds to about 30 per cent of the total nitrogen absorbed, rising to 40 per cent in the more highly bleached samples. After the lapse of several days, the proportion of nitrites present decreases considerably in the higher concentrations, but remains very nearly the same in the more slightly bleached samples.

"Approximately 60 per cent of the total nitrogen introduced as nitrogen peroxid into the flour during bleaching can be recovered as ammonia a short time after bleaching by reducing the aqueous extract of the flour with a copper-zinc couple, and may be assumed to be present in the flour as nitric and nitrous acids or as nitrates and nitrites. After keeping the bleached flour for some days the amount of nitric acid extracted with cold water decreases. Experiments with pure glutenin and gliadin indicated that in certain circumstances nitric acid may be withdrawn from solution or 'absorbed' by these proteins.

"In highly bleached flour a considerable increase in the amounts of soluble proteins and soluble carbohydrates takes place. If 1 kg. of flour is bleached with 300 cc. of nitrogen peroxid, the amount of soluble nitrogen is doubled. This appears to be due almost entirely to the solubility of gliadin in nitric acid of certain concentrations. The simultaneous increase of soluble carbohydrates would seem to point to an intimate relationship between the gliadin and certain carbohydrates in flour.

"If highly bleached flour is allowed to stand for some time after bleaching, the oil undergoes very considerable alteration and acquires the characteristics of an oxidized oil. About 6 to 7 per cent of the nitrogen introduced as nitrogen peroxid during bleaching is absorbed by the oil.

"The absorption of nitrogen peroxid by flour does not appear to be accompanied by the production of free nitrogen, nor was any evidence obtained of the formation of diazo-compounds.

"Sodium nitrite was found to exert no inhibitory action on the digestion of soluble starch by saliva, but the rate of digestion was greatly retarded if the starch had been previously treated with nitrogen peroxid gas. Bleaching was found to exercise an inhibitory effect on the salivary digestion of flour."

A report by Harden is appended, On Certain Experiments in Relation to Bleached Flour carried out at the Lister Institute, in which samples bleached by a commercial electrical process were used as well as overbleached samples prepared in the laboratory. The data regarding the amount of nitrite-reacting material in overbleached flours show "that the sodium nitrite content of overbleached flour varies very considerably with the time. It would appear probable that the nitrous gases first of all dissolve in the water of the flour and then gradually undergo a change which destroys their nitrite-reacting power."

In grossly overbleached flours the amount found was considerably less than that present in flours "treated with much less NO₃, and indicates that some different or more intense reaction occurs under the conditions of the preparation of this sample [of grossly overbleached flour]."

In tests for the presence of nitrogen in diazo-form no definite evolution of gas could be observed.

"It was found very difficult to remove all the air from the flour and the results were therefore not very accurate. They show, however, conclusively that no considerable proportion of the nitrous gas goes to form diazo-compounds capable of being decomposed with evolution of nitrogen by boiling hydrochloric acid. The equivalent of sodium nitrite present in the flour at the time of the experiment was 22.8 parts per million, so that the nitrogen obtainable by the action of the corresponding nitrites on the proteins of the flour for a quantity of 20 gm. would be 0.15 cc."
In artificial digestion experiments it was found that overbleached flours underwent a slightly greater degree of tryptic digestion than unbleached flour.

"It may be concluded from these results that the bleaching of flour does not in any degree diminish the readiness with which it undergoes tryptic digestion in vitro."

As regards peptic digestion, the author's results "show a decided, although small, inhibition in the digestion of the bleached samples, the numbers given by these in 4 hours being decidedly less than those of the unbleached. At the expiration of 22 hours this difference had disappeared."

The author's experiments, which have to do with the rapidity of digestion, confirm the observation that "the gluten of unbleached flour is much the more rapidly dissolved. . . . In view of the results obtained with flour with which the rates of solution are only slightly different, it would seem that the effect is due rather to some change produced in the physical properties of the gluten obtainable from the flour than to the formation of a less readily digested compound."

Experiments were also made in which overbleached flour and aqueous extracts of grossly overbleached flour and of commercially bleached flour were administered to small animals (rabbits and a cat).

The results showed that "the extract from commercially bleached flour, from overbleached flour, and even that from grossly overbleached flour is apparently harmless to animals under the above conditions."

A list of references follows the paper, and a quotation in full of U. S. Department of Agriculture Food Inspection Decision No. 100 (E. S. R., 20, p. 863).

On the bleaching of flour and the addition of so-called "improvers" to flour. J. M. Harrell (Rpts. Local Gorl. Bd. [Gt. Brit.], Publ. Health and Med. Subjhs., n. ser., 1911, No. 39, pp. 1-33; rev. in Brit. Med. Jour., 1911, No. 2624, pp. 881, 882).—In this digest of data, which includes the author's own laboratory work and personal observations in mills and bakeries, as well as the reports of other investigators, the source of supply of wheat and flour, milling and grading, factors which determine quality, bleaching processes, their effects, the addition of so-called "improvers" in flour, and similar matters are considered. The general conclusions reached are unfavorable to bleaching and to the use of so-called "improvers."

"The alterations in and the additions to flour which result from a high degree of bleaching by nitrogen peroxid can not be regarded as free from risk to the consumer, especially when regard is had to the inhibitory effect of the bleaching agent on digestive processes and enzymes. Even in the case of flour which is bleached to the small extent which is at present ordinarily practiced, it would in present knowledge be unwise to conclude that the process is attended by absolute freedom from risk. The fact that bleached flour has been shown to be something more than natural flour, the color of which has been modified, is also of importance in considering whether bleached flour may properly be represented as genuine flour. . . ."

"With regard to other substances which have been represented as 'improvers,' it may be said that the indiscriminate addition of powerful chemical substances, such as hydrofluoric acid, phosphorus pentachlorid, and the oxides and sulphids of phosphorus, to flour is most dangerous."

The author states that the use of cereals other than wheat in the milling of flour is not common in England, though he cites an instance of the addition of maize to flour and to-self-raising flour.

"The increasing activity which is now being displayed in the use of different articles as additions to flour must be regarded with considerable apprehension. It does not appear desirable that such an indispensable foodstuff as flour, the
purity and wholesomeness of which are of first importance to the community, should be manipulated and treated with foreign substances, the utility of which, from the point of view of the consumer, is more than questionable."

According to the author's conclusions, "acid calcium phosphate of the lowest commercial quality containing large proportions of calcium sulphate as an impurity is used to a considerable extent by makers of self-raising flour, confectioners, wholesale cake makers, etc. Less commonly this low-grade phosphate is an ingredient of baking powders sold as such to the public. Where the maker concerned buys his acid phosphate as such, and selects the lowest grade as the cheapest, he may obtain a slight additional profit from its employment, which, however, may be counterbalanced by the lower efficiency of the article. It does not appear that the consumer derives any benefit; on the contrary, he is liable to be prejudiced by the use of this material. . . .

"If acid phosphates of relatively low commercial quality and purity are used in food preparation, the interests of the majority of the traders concerned, as well as those of the public, would be served by the existence of an understanding as to the degree of impurity which should entail their rejection as food ingredients."

A number of recommendations are made which would lead to improved conditions.

Appended to the paper is a report by C. H. Cribb on the alleged utility of calcium sulphate in "phosphate" baking powders. From a consideration of the data presented the author concludes that "the presence of much calcium sulphate in the residue left by the powder after it has done its work in the loaf seems to be unavoidable. The statement that it is converted into the easily soluble sodium sulphate is not borne out by experiment. A portion of a loaf baked with a powder containing pure acid calcium phosphate, calcium sulphate, and sodium bicarbonate far in excess of the neutralizing power of the phosphate, was dried, very finely powdered, and shaken up with chloroform. A heavy sediment of mineral matter was obtained which contained no calcium carbonate, and in which only ¼ of the total combined sulphuric acid was present as sodium sulphate.

"To whatever extent the formation of sodium sulphate may occur during baking, the ultimate fate of the combined sulphuric acid is to be reconverted once more into calcium sulphate when it reaches the stomach. A mixture of tri-calcium phosphate, sodium sulphate and excess of dilute hydrochloric acid of the strength of the gastric juice, after standing for a short time, was found to contain a residue insoluble in strong acid and consisting, as would be expected, entirely of calcium sulphate."

Nutrition investigations on the carbohydrates of lichens, algae, and related substances, Mary D. Swartz (Trans. Conn. Acad. Arts and Sci., 16 (1911), pp. 247-382).—The investigations reported have been noted from a summary previously published (E. S. R., 24, p. 367).

Experimental studies of the preservation of horse meat by low temperature and its use as food, A. Costa and N. Mori (Clin. Vct. [Milan], sez. Prat., 33 (1910), NOS. 50, pp. 793-797; 51, pp. 809-813; 52, pp. 830-832).—Experimental studies are reported and discussed.
Do Paratyphus-like bacteria occur in meat under normal conditions, and if so, is bacteriological meat inspection necessary? C. Bongartz (Kom- men normalerweise im Fleisch unserer Schlachttiere paratyphus-ähnliche Bakterien vor und bedeutet der Nachweis derselben die Einführung der bacteriologischen Fleischbeschau? Inaug. Diss., Univ. Bern. 1910, pp. 36).—Studies were made with samples of meat including that from normal animals, condemned animals, organs, sausage, and other meat products. Micro-organisms were found in a number of the samples, including bacteria of the Paratyphus type. The data are discussed with reference to meat inspection.

In general, the author suggests that an educational campaign is desirable which would point out the necessity for cooking meat and meat products instead of eating them raw or half-cooked.

Food inspection decisions (U. S. Dept. Agr., Food Inspr. Decisions 134–135, p. 1 cach).—These two decisions have to do, respectively, with the labeling of New Orleans molasses, and saccharin in food.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 806, pp. 6; 807–808, pp. 2 cach; 811, pp. 2; 813–814, p. 1 cach; 815, pp. 2; 816, pp. 3; 817–819, p. 1 cach; 820–821, pp. 2 cach; 822, pp. 3; 823, pp. 6; 824, pp. 2; 825, pp. 4; 826–828, p. 2 cach; 829, p. 1; 830, pp. 2; 831, p. 1; 832, pp. 3; 833, p. 1; 834, pp. 2; 835, pp. 3; 837, pp. 2; 838, p. 1; 839, pp. 3; 840–841, pp. 2 cach).—These notices of judgment have to do with the adulteration of crackers, figs, ice cream cones, olives, tomato catsup, a frozen egg product, tea, prunes, and catsup; the misbranding of flavoring extracts, olive oil, Londoonderry lithia water, drug products, sparkling Burgundy and champagne, and mineral water; the adulteration and misbranding of lemon extract, fruit jellies, vinegar, port wine, tomato catsup, alleged temperance drinks, pepper, bitters, coffee, and vanilla extract; and the alleged misbranding of a drug product.

Official inspections (Maine Sta. Off. Inspr. 30, pp. 37–44).—The results are given of the examination of a large number of samples of oysters, pork sausage, and clams. The question of imitation beer with reference to the Maine Food and Drug Law is also discussed.

[Food inspection], W. D. Saunders (Dept. Agr. and Immigr. Va., Dairy and Food Div. Bull. 14, pp. 86–117).—The results are reported of the examination under the state dairy and food commission of a large number of samples of baking powder, beverages, buckwheat flour, condensed milk, and other dairy products, egg substitutes, spices, vinegar, and miscellaneous food materials.

Composition of East Indian food materials, M. Greeshoff (Bul. Kolon. Mus. Haarlem, 1910, No. 45, Sup.).—Continuing earlier work previously noted (E. S. R., 19, p. 163), the author reports analyses of a large number of samples including among others grits, cereal breakfast foods, infant foods, cottonseed meal, cola nut, dried fruits, nuts, Iceland moss, Irish moss, curcumia root stalk, Sicilian manna (Fraxinus ornus), milk, and milk products.

[Food of Patagonian natives], C. W. Furlong (Harper’s Mo., Mag., 122 (1911), No. 782, pp. 813–827, pl. 1, figs. 9, maps 2).—In an account of the customs and living conditions of the Teluelches of the Patagonian pampas the author gives some data regarding food conditions. Apparently, these natives live very largely upon the meat of mares and game.
The food of families of Danish laboring men, P. Heiberg and Maria V. Jensen (Zentr. Gesam. Physiol. u. Path. Stoffwechsel, n. scr., 5 (1910), No. 12, pp. 443-461).—From data recorded in papers left by Schierbeck, and based on the statistical study of laborers’ families in Denmark, the authors discuss living conditions in the families of Danish laboring men, including the proportionate expenditure of the income for food and other necessaries, and the nutritive value of the diet.

The conclusion is reached that the daily food of the Danish laborer supplies on an average 107 gm. protein, 105 gm. fat, and 493 gm. carbohydrates, the energy value being 3,450 calories.

A suggestion for an emergency ration, C. Ryley (Jour. Roy. Army Med. Corps, 15 (1910), No. 5, pp. 595, 596).—The author suggests that cheese, hard biscuit, and a small portion of desiccated soup powder would make a satisfactory emergency ration. The cheese should be in the form of a small block weighing ½ lb., separately molded, and paraffin coated to prevent decomposition in transportation and in tropical climates.

Observations on the minimum amount required for maintenance, A. Loewy and F. Hirschfeld (Dent. Med. Wochenschr., 36 (1910), No. 39, pp. 1794-1797).—Though undertaken with special reference to the study of constitutional corpulency, the experimental data are of interest in connection with questions of general nutrition.

The constancy of metabolism for maintenance in healthy man, A. Loewy (Dent. Med. Wochenschr., 36 (1910), No. 39, pp. 1797, 1798).—The author summarizes and discusses data which have to do particularly with oxygen consumption.

The digestion of fat in the stomach and small intestine and the influence of lecithin upon it, Usuki (Arch. Expt. Path. u. Pharmacol., 63 (1910), No. 3-4, pp. 270-293).—Some of the conclusions from the author’s investigations made with a child 9 weeks old follow.

Digestion took place more slowly when milk was fed than was the case with milk with lecithin or with egg yolk, these mixtures leaving the stomach from 1½ to 2 hours sooner. More soaps were found in the intestinal contents on the milk diet than on the milk-lecithin diet, and less than on the egg-yolk-milk diet. Lecithin undergoes cleavage in the stomach more quickly than neutral fats. The presence of lecithin has a favorable action upon the saponification of neutral fats. Although the percentage of lecithin was smaller, yet the digestion of fat on the egg-yolk-milk diet was fully as satisfactory as on the lecithin-milk diet.

No lecithin was found in the intestine. It must therefore have undergone cleavage in the stomach or immediately after entering the intestine.

The rôle of hypophysis in nutrition, F. Duncan (Presse Méd. [Paris], 1911, No. 31, pp. 312-314).—Experiments with animals (rabbits) are reported on the effects of hypophysis on nutrition, body temperature, respiration, and other physiological factors. The administration of this material, according to the author, produced, among other effects, rapid loss in weight, increased blood pressure, a lowered elimination of nitrogen, and glycosuria.

MAGNESIUM and calcium metabolism in] chorea (St. Vitus's dance),
J. AULEE (Reprint from N. Y. Med. Times, 1911, Mar.–Apr., pp. 16).—"This discussion of pathological conditions contains data of interest in connection with the general question of mineral metabolism.

The question of mineral matter in the diet, particularly with reference to the health of children, is taken up, as are other similar topics.

The reactions between chemical compounds and living muscle proteins,
V. H. VELEY (Jour. Chem. Soc. [London], 99 (1911), No. 589, pp. 180–191, dgm. 1).—When a living muscle is immersed in solutions of certain compounds the author found that "a chemical change takes place between the solute and the muscle proteins or their initial hydrolysis products; its rate can be measured by the heights of response to induction shocks used as an indicating record..."

"If the hypothesis be correct that the chemical changes discussed... are due to a reaction between the compounds whether acid or base, and the polypeptides, either formed by hydrolysis of the muscle protein or present by virtue of the moribund condition of the muscle, then amino acids in not too highly concentrated solution should produce no effect. Results are given in the case of amino acetic acid in proof of this line of argument."

[Work of the Carnegie nutrition laboratory], F. G. BENEDICT (Carnegie Inst. Washington Year Book, 9 (1910), pp. 179–191; reprint).—An account is given of the improvements and changes made in the laboratory equipment, the investigations now in progress are described, and abstracts are presented of papers which have been published during the year.

ANIMAL PRODUCTION.

Feeding stuff inspection (Maine Sta. Off. Insp. 31, pp. 45–64).—Analyses are reported of meat scrap, cottonseed meal, linseed-oil meal, gluten feed, distillers' grains, wheat offals, molasses feed, hominy feed, dried-beet pulp, corn meal, and proprietary mixed feeds. A discussion of a recent amendment to the state feeding stuff law and a list of commercial feeds containing whole weed seeds are also given.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 809, 810, pp. 2 each).—These relate to the misbranding of stock feeds.

Adulteration of linseed cakes and linseed meals in Belgium, L. BUSSARD (Ann. Falsif., 4 (1911), No. 27, pp. 30, 31; abs. in Analyst, 36 (1911), No. 322, p. 218).—The principal adulterants of linseed meal in the samples examined were sand and by-products of rice, cottonseed, peanuts, and flaxseed.

The energy of digestion and the specific dynamic effect of feeding stuffs,
N. ZUENTZ (Med. Klinik, 6 (1910), Nos. 8, pp. 309, 310; 9, pp. 351–354; Separate, pp. 1).—This is a summary of recent investigations on this subject.

The dextrose of the egg and its biological significance,
V. DIAMARE (Rend. Accad. Sci. Fis. e Mat. Napoli, 3, scr., 16 (1910), pp. 242–244; abs. in Jour. Chem. Soc. [London], 100 (1911), No. 580, II, p. 129).—The eggs of the domestic fowl and of the Grecian tortoise when approaching maturity in the ovary contain dextrose, of which equal amounts were removed by dialysis and hydrolysis, respectively. In the younger eggs the proportion of dialyzable sugar was less and in the very smallest eggs no reducing sugar was present.

On the constitution of the metacarpus in warm and cold blooded horses,
J. H. W. T. REIMERS (Cultura, 22 (1910), No. 268, pp. 599–611, fig. 1).—This
contains data on the length, breadth, and thickness of the walls of the cannon bone in horses. The bones were also examined chemically and microscopically.

A bibliography is appended.

The law of the origin of the sex and the means by which the sex of the individual is influenced, I. Sutkowski (Berlin, Klinik, 1909, No. 252, pp. 1–7; abs. in Arch., Rassen u. Gesch. Biol., 7 (1910), No. 2, pp. 241, 242).—Various theories on this subject arc reviewed and a new theory proposed, based on the belief that the sex of the embryo is dependent upon the chemical reaction of the medium through which the spermatozoa passes on its way to the egg, as it is very sensitive to change, losing its motility in acids and regaining it in alkalis. It is also claimed that an acid medium causes a production of females and an alkaline medium the production of males.

Kinematography of fertilization and cell division, G. J. Ries (Arch. Mikros. Anat. u. Entwicklungsgeschichte, 27 (1909), No. 1, pp. 1–31, pls. 2, figs. 12).—This contains information on the use of the kinematograph, by means of which a continuous picture can be obtained of all stages and changes in the spermatozoa, unfertilized egg, cell division, and the early stages of development of the fertilized eggs.

On the influence of the spermatozoa on the uterus, J. H. F. Kohlbrugge (Ztschr. Morph. u. Anthropol., 12 (1909), No. 2, pp. 359–368, figs. 2; abs. in Arch., Rassen u. Gesch. Biol., 7 (1910), No. 2, pp. 250, 251).—The sex organs of 1,300 Javan bats were examined and large numbers of spermatozoa were found in the epithelium of the uteri and adjoining tissues. The author thinks that the penetration of millions of spermatozoa into the mucosa uteri of great importance, as it may produce an effect similar to that caused by injections of serum, with the possibility that the biochemical changes of the uterine tissues in turn may affect the growing embryo, in which case somatic changes of the embryo would furnish a demonstration of telegony though not necessarily the inheritance of acquired characters.

The influence of the spermatozoa on the blastula, J. H. F. Kohlbrugge (Arch. Mikros. Anat. u. Entwicklungsgeschichte, 73 (1910), No. 3, pp. 519–524, fig. 1; abs. in Zentbl. Allg. u. Expft. Biol., 1 (1910), No. 9–10, p. 337).—Additional experiments on the bat showed that the spermatozoa penetrated the blastula and the embryonic disk after the zona pellucida was ruptured. The author suggests that the sperm entered the developing ova from 8 to 10 days after fertilization, and thus the male may have influenced the embryo apart from amphibimixis.

Experimental contributions on abortion and sterility induced by Roentgen rays, F. Trillmich (Experimenteller Beitrag zur Einleitung des künstlichen Abortus und zur Sterilisation durch Röntgenstrahlen. Inaug. Diss., Univ. Freiburg, 1910, pp. 62; abs. in Zentbl. Gesamm. Physiol. u. Path. Stoffwechselns, n. s., 6 (1911), No. 8, p. 352).—Exposure to Roentgen rays caused abortion and sterility in a large percentage of the guinea pigs so treated.

A note on zebra hybrid breeding, E. H. Riley (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 229–232, pls. 3).—A summary is given of previous attempts by various investigators to obtain zebra hybrids, and a brief report is made of the zebra hybrids which have been obtained at the Bureau experiment station, the data presented being substantially those previously noted from another source (E. S. R., 23, p. 671).

annual report, containing information which includes a review of the live stock market in 1909, meat prices at home and abroad, the foreign trade in animals and animal products, federal meat inspection, and data as to the number of live stock registered in the United States, certified pedigree record associations, national and state stock breeders’ associations, legal standards for dairy products, contagious diseases of animals in foreign countries, and a list of state live stock sanitary officers.

Information for importers of animals for breeding purposes, G. A. Bell (U. S. Dept. Agr., Bur. Anim. Indus. Circ. 177, pp. 3).—This contains details of the procedure and requirements under the law and the regulations providing for the importation of animals free of duty for breeding purposes, including the text of that portion of the tariff act of August 5, 1909, relating thereto.

Minutes of evidence taken before the departmental committee on agriculture and live stock, Scotland (Edinburgh: Govt., 1911, pp. 133).—This reports the evidence obtained by a committee of inquiry appointed by the secretary of Scotland to inquire and report upon what has been done in the past for the improvement of live stock and agriculture in the congested areas, and to find out what remedies, if any, can be applied to improve the live stock conditions.

British breeds of live stock (London: Govt., 1910, pp. 137, pls. 45).—The characteristics of all breeds of live stock, including poultry, common to the British Isles are described. A list of breeding societies, with average prices and places of sale of animals of each breed, is appended.

Cattle raising in Russia, P. A. Pakhomov (Ezhov. Dept. Zeml. [Russia], 30 (1909), pp. 426–458, pls. 4).—The present state of cattle raising in Russia is considered from an economic point of view. Measures for improving the stock and methods of feeding and management are discussed.

Feeding experiments with cattle and sheep, 1907–1910, D. A. Gilchrist (County Northumb., Ed. Com., Bul. 15, pp. 33).—This is a summary of feeding tests which have been previously noted from various sources.

Improvement of hill pasture as determined by the effect on stock, J. Hendrick (Trans. Highland and Agr. Soc. Scot., 5. ser., 23 (1911), pp. 199–216).—This is the third and final report of a series of experiments on improving poor hill pasture by the application of manures and by feeding cake to cattle and sheep, which were begun in 1901 and continued for 10 years. The 4 experiments in the west of Scotland were discontinued at the end of the seventh season. The three localities, Sunderland Hall, Boon, and Naemoor, in the east of Scotland, differed from one another markedly in soil and situation, but gave results which agree in the main points. In certain respects the results were dissimilar to those reported by Somerville (E. S. R., 25, p. 75), but this was to be expected as the soils and conditions are dissimilar.

The main result with these experiments is to support the view that the chemical constituent most needed by such poor pastures is superphosphate in a basic form combined with an excess of lime, but the extraordinary results obtained with slag at Cockle Park were not obtained.

“The lime-phosphatic manures—(a) basic slag and (b) superphosphate applied along with lime—have in every case effected a marked and long-continued improvement on the pastures on which they were applied. Basic slag applied alone has on the whole given the best return of all the manures. Potash used along with basic slag has not generally paid its way. Even in the case of basic slag, on an average 3 or 4 years elapsed before sufficient result was obtained to pay for the slag. . . . Though a dressing of superphosphate and lime effected a considerable improvement, it did not pay so well as basic slag. The original cost of the dressing was greater, and on the average the return obtained
was not greater than that from slag alone. The effect of the dressing was not exhausted in 9 years.

"The feeding of cake gave the worst return of all for the expenditure. In no case did it pay, either in the direct increase made by the sheep or in the improvement effected in the pasture. Generally speaking, very little result is recoverable on these soils from the manure residue of the cake used.

"When the soil is covered with a very thick coarse sod of grass of poor quality, clover plants and the fine grasses have not room to develop, and the effect of the manure is shown only very slowly. On such pasture sheep alone are unable to eat down the grass properly, and better results are obtained when sheep and cattle are grazed on the same land. On such land cattle make far greater live weight increase per acre than sheep."

[Experiments with sheep], T. R. Arkell (New Hampshire Sta. Bul. 151, pp. 32–38).—A report of progress of work in sheep breeding and feeding begun in 1908. The breeds used were Dorset, Hampshire, Shropshire, Southdown, Merino, Leicester, and Rambouillet. Records are kept of 26 characteristics for each sheep. The present report treats of the results obtained with the F₁ generation only. "The F₁ heterozygotes produced from a cross between sheep possessing respectively very dark and pure white hair color usually present a mosaic appearance. However, in every instance there is a clear preponderance of the black color. It also appears from experimental evidence we have on hand that skin pigmentation in sheep is inherited in a similar fashion."

The inheritance of horns agrees with the results obtained by Wood (E. S. R. 22, p. 378). An extended distribution of wool about the face, ears, and legs appears to dominate over the less extended or sparser covering. Skin folding appears to be dominant over the smooth skin, and white wool dominant over black. The best results obtained in raising early lambs were the crosses of the Hampshire or Shropshire ram on Merino, Merino grade, or Desert Horn ewe. The early lambs shrank in dressing from 50 to 55 per cent.

A brief report is made of a feeding test, details of which will be given in a forthcoming bulletin.

The differences between the skeleton in normal and abnormal animals are pointed out. Castration of lambs at 1 month of age lengthens the neck and the long bones, shortens and broadens the os innominatum, inhibits the growth of horns, changes the skull in many ways, and affects the weight and height of the different parts of the body disproportionately.

Periodic migration in Spain, A. Fribourg (Ann. Géogr., 19 (1919), No. 105, pp. 231–244, pls. 2, figs. 3).—This discusses the climatic and economic conditions which have affected the periodic migrations of flocks of sheep between winter and summer pastures. The distribution of sheep and the routes of migrating flocks are illustrated by maps.

Sheep raising in Russia, R. R. Pravokhenski (Ezheg. Dept. Zeml. [Russia], 30 (1909), pp. 429–434, charts 5).—A historical survey of the development of sheep raising in Russia, and a description of the present condition of this industry. According to the best available statistics in 1909 European Russia contained 85,000,000 sheep, or 34 sheep to every 100 persons.
[Lamb shearing experiments in New Zealand] (Jour. New Zealand, Depl. Agr., 1910, No. 3, pp. 217; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Int'l. and Plant Diseases, 1910, Nov., p. 123).—Twenty lambs were divided into 2 lots, one lot of which was shorn. At the end of 6 months the unshorn lot had gained in weight 35 lbs. more than the other, and at the end of 9 months 75 lbs. Later, when the 2 lots were shorn, the unshorn lot gave an average of 2.1 lbs. more wool than the other.

Corn, soy-bean pastures, tankage and cotton-seed meal for fattening hogs, D. T. Gray, J. W. Ridgway, and E. R. Eudaly (Alabama Col. Sta. Bul. 154, pp. 45-87, figs. 14).—A report of 3 years' work in feeding 105 hogs in order to determine (1) the value of soy-bean pasture as compared with other feeds, (2) the most profitable amount of corn to be fed as a supplement, and (3) the effect of soy-bean forage on the quality of the pork.

When corn was used alone the average daily gain for each hog was 0.375 lb. at a cost of 7.63 cts. When a soy-bean pasture was grazed with a one-fourth, one-half, and three-fourths ration of corn the average daily gains were raised to 1.192, 1.096, and 1.223 lbs., respectively, and the cost of the pork reduced to 2.50, 3.35, and 3.17 cts. per pound, respectively. One acre of soy-bean pasture afforded grazing for 10 hogs for 45 days when a one-fourth ration of corn was fed, 48 days on a one-half-ration of corn, and 62 days on a three-fourths ration of corn. The total value of pork made on each acre of soy-bean pasture varied from $25.84 to $39.13.

Tankage and cotton-seed meal proved to have about equal feeding value, as supplements to corn in the dry lot. It proved profitable to enclose the hogs in a dry lot after the pasture crops were exhausted and to feed for a short time on grain.

A summary of Bulletin 143, previously noted (E. S. R., 20, p. 569), is included.

Origin of the Clydesdale and other heavy breeds of horses, J. C. Ewart (Trans. Highland and Agr. Soc. Scot., 5. ser., 23 (1911), pp. 151-169, figs. 16).—From studies of the skulls, teeth, limbs, etc., of fossil and living horses, the author concludes that the modern heavy English breeds have been the result of a blend, in most cases of 3 distinct wild races, namely (1) a large, robust, broad-browed race, with a straight or dished face, and with stout limbs adapted for a forest life; (2) a race in build not unlike certain modern thoroughbreds, characterized by a face bent downward on the cranium, a prominence between the eyes, long limbs, well-laid shoulders, high withers, and a high set-on tail; and (3) a race highly specialized for a steppe life, characterized by a long, narrow face, and, as in many steppe forms, by large nasal chambers (which imply a "Roman nose"), by clean limbs, close hocks, and a wonderful power of clearing obstacles.

Breeding horses for the United States Army (U. S. Depl. Agr., Bur. Anim. Indus. Circ. 178, pp. 13).—The information contained in this circular is taken from the report of the chief of the Bureau of Animal Industry for 1910, previously noted (E. S. R., 25, p. 95). It is claimed that the supply of horses fit for army remounts has become so limited as to make it necessary for the Government to encourage the breeding of army horses. A brief outline is given of the plan proposed for the purchasing of stallions and the proposed method of breeding.

Marketing eggs through the creamery, R. R. Slocum (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 219–246; Farmers' Bul. 435, pp. 12).—This contains information on methods of marketing eggs, including an account of the system followed by a creamery in northern Minnesota in handling them. Among the advantages found have been an increased price for the eggs and a decided improvement in their quality.

The sanitary construction and equipment of abattoirs and packing houses, G. H. Parks (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 247–263, pl. 1, fig. 1; Circ. 173, pp. 247–263, pl. 1, fig. 1).—In this paper the author deals with the principles and sanitary features of abattoir construction.

"All buildings that are to be used for the purpose of slaughtering animals for the preparation of meat or meat food products should meet the following requirements: (1) A location on a site that is dry and with an aspect which gives an abundance of sunlight; (2) an abundant supply of pure water, by means of which perfect cleanliness of all parts of the building can be secured, and proper means for the removal of waste water; (3) a system of immediate and perfect sewage removal which renders it impossible that the air or water shall be contaminated; (4) a system of ventilation which carries off all impurities from the air of the rooms and supplies clean, pure air as required; (5) a condition of building construction which admits of perfect cleanliness of the ceilings, columns, walls, and floors; and (6) proper equipment."

DAIRY FARMING—DAIRYING.

Report of the activities of the dairy institute at Hameln, 1910, P. Vierth (Ber. Milchw. Inst. Hameln, 1910, pp. 25).—This contains brief reports on trials of separators and other dairy apparatus, and analysis of milk, butter, and cheese.

Cow-testing associations, H. Rabild (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 99–118; Circ. 179, pp. 24).—This gives an account of the origin of the cow-testing associations in Denmark in 1892 and the growth of the movement in other countries. Their value to the dairy industry, as shown by the records of the associations, is pointed out, and methods of organizing the farmers and testing the herds are discussed. Special attention is given to the work
of the associations in the United States, which has been encouraged by this Department. Forms for a constitution and by-laws of the association and the contract used in organizing it are given.

The influence of food on the composition of milk, A. Ciccarelli (Gior. R. Soc. Ital. J., 31 (1909), No. 7, pp. 308–319; abs. in Milchw. Zentral., 6 (1910), No. 9, p. 428).—The addition of beef chips to a normal ration did not appear to affect the composition of the milk, but an exclusive beef chip diet caused the milk to be poor in protein and fat. Such milk is not recommended for feeding infants.

On factors influencing the functional activity of the mammary gland, G. v'Enrico (Pediatrica [Naples], 18 (1910), No. 4, pp. 253–266; abs. in Rev. Hyg. et Méd. Infant., 9 (1910), No. 5–6, pp. 541, 542).—The author’s experiments with dogs indicate that a ferment is produced in the fetal membrane which causes hypertrophy of the mammary gland. An intravenous injection of defibrinated blood obtained from a pregnant dog inhibited milk secretion of a lactating female dog, but the blood of a normal animal did not have this effect.

Fermented milks, L. A. Rogers (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 123–161, fig. 1; Circ. 171, pp. 133–161, fig. 1).—This contains a summary of investigations on the biology and therapeutic value of fermented milk preparations sold under various trade names, as zoulak, vitallac, yoghont, matzoon, bacilla, kefir, koumiss, and lactobacillin. The methods of preparation are discussed, and a bibliography of 76 titles is appended.

Notices of judgment (U. S. Dept. Agr., Notices of Judgment 812, pp. 2; 836, p. 1; 845, pp. 2).—These relate to the adulteration of butter and condensed milk.

The extra cost of producing clean milk, G. M. Whitaker (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 119–131, pls. 4, fig. 1; Circ. 170, pp. 119–131, pls. 4, fig. 1).—The aim of this article was to furnish accurate statements as to what modern sanitary milk means and the extra cost to the dairyman. Some of the conclusions are as follows:

"To increase the score of a dairy from 42 to approximately 70 points, there may be in 15-cow dairies an added expense of 5 cts. per cow per day for labor, plus, in extreme cases, 5½ cts. for new or additional equipment; and if we add 5 cts. more to remunerate the proprietor for his extra care and vigilance, there will be an extreme increase of 15½ cts. per cow per day. The product of a cow ranges from 4,000 to 10,000 lbs. of milk a year, or from 5 to 12 qts. a day. The added expense for labor would, therefore, amount to about half a cent to 1 ct. a quart, and in the rare instances where great additional expense is required for repairs, new construction, and new equipment this might raise the increase 1 to 2 cts. a quart more. . . . This added expense of improved methods and equipment, however, would no doubt be partly offset by increased production and increased economy of feed, so that the net extra expense of producing clean milk would probably be somewhat less than the figures given. . . . A reasonably clean milk is worth 2 cts. more than common slovenly milk. The former is safer, and therefore cheaper, at the increased price. " Dirty milk ought not to be considered a merchantable article at any price, no matter how low."

Some of the conclusions drawn are the following: "The evidence we have to prove that tubercle bacilli derived from cattle cause tuberculosis—and fatal tuberculosis—among human beings is direct and irrefutable. The evidence we have to prove that the milk from tuberculous dairy herds frequently contains living virulent tubercle bacilli is equally direct and irrefutable. Hence no medical milk commission should consent to the certification of milk unless it is obtained from cows that are free from tuberculosis and that are kept in an environment free from tuberculosis infection. . . . Pasteurization should be recommended for all milk that is not certainly free from the germs of tuberculosis or those of other diseases . . . . Until commercial pasteurization has been placed under official supervision, home pasteurization seems to be the best solution."

In a study of the presence of streptococci and tubercle bacilli, subcutaneous inoculations were made on guinea pigs. In the ordinary market milk, many cases where the pigs died of septic peritonitis a microscopic examination revealed the presence of streptococci. Of 123 samples of market milk with which inoculations were completed, 18 were found to contain tubercle bacilli, or 14.6 per cent. It is stated that if all the experimental animals had lived sufficiently long for the lesions to develop the percentage found would probably have been even higher.

In "pasteurized" milk obtained from dealers known to have pasteurizing machines the number of bacteria present in most of the samples indicated that either the milk was not properly pasteurized or that it was placed under bad conditions after the process was completed. Inoculations showed that 1 sample out of 12 contained virulent tubercle bacilli. In other market milks claimed to be pasteurized a large number of bacteria were found, and the great increase in the count of leucocytes after heating to 60° C. suggested that pasteurization had not been practiced in the majority of the samples. Inoculations of these milks likewise showed that 1 sample out of 12 contained virulent tubercle bacilli.

"The method of commercial pasteurization used in the trade can not be relied upon as a means of destroying disease-producing bacteria. If pasteurization is to be used as a means of purifying milk, it should be done under legal regulation and official supervision. A microscopic examination for determining the presence of tubercle bacilli in milk is of little value."

The viability of tubercle bacilli in butter, J. R. Mohler, H. J. Washburn, and L. A. Rogers (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 179–185, fig. 1).—Butter was made from milk inoculated with tubercle bacilli, packed in glass jars, and sent by express to Chicago. After remaining in storage for periods varying from 10 days to 6 months, guinea pigs were fed the butter and others were inoculated with it.

It was found that the storage of butter at ordinary temperatures during a period approximating the length of time that market butter is usually held will not destroy the vitality of tubercle bacilli within the product. The experiments also indicated that the organisms were not distributed uniformly throughout the product, and it is stated that the test should cover a considerable length of time, since negative results may lead to erroneous conclusions if not properly controlled by subsequent experiments. For example, certain samples failed to cause tuberculosis in the experimental animals when the butter was
10 days old, while other samples from the same lot but 90 days old produced tuberculosis. The most highly infectious lot was butter made from milk secreted by a tuberculous udder. The inoculation of guinea pigs with products suspected of being tuberculous was found to be a more delicate test than the feeding experiments.

The inference drawn from this work is that the most satisfactory way of producing sanitary or certified milk would be to manufacture butter only from cream that is free from tubercle bacilli. Though the application of the tuberculin test is desirable, pasteurization should be resorted to where it is not practicable. No dependence can be placed on the germicidal action of salt.

The viability of tubercle bacilli in cheese, J. R. Mohler, H. J. Washburn, and C. F. Doane (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 187-191).—Cheese made from milk which had been inoculated with tubercle bacilli was ripened at a temperature of about 65° F. for 7 days, then put into tin cans and placed in cold storage at about 32° F. At periods ranging from 23 to 283 days from the day the cheese was made it was used for feeding and for inoculating guinea pigs.

None of the animals used in testing the cheese when it was 23 days old developed tuberculosis, either in those inoculated or in those fed, but generalized tuberculosis was more or less prevalent in the lots fed or inoculated when the cheese was from 33 to 261 days old. The results were again negative in all cases after the cheese was 297 days old. As in the case of the investigations in butter (noted above), the bacilli were found to be irregularly distributed.

As a result of these experiments it is evident that tubercle bacilli remain virulent in cheese for a considerable period of time, and that cheese made from raw unpasteurized milk should be considered a possible carrier of tubercle bacilli. It is recommended that some steps be taken to prevent the introduction of living virulent tubercle bacilli into this important food, either by subjecting all cows to the tuberculin test or by pasteurizing the milk.

VETERINARY MEDICINE.

Results of investigations in the field of general pathology and pathological anatomy of man and animals, edited by O. Lubarsch and R. Oster tag (Ergeb. Allg. Path. Mensch. u. Tiere, 12 (1908), pp. X+891; 13 (1909), pts. 1, pp. IX+629; 2, pp. VIII+694; 14 (1910), pts. 1, pp. X+771; 2, pp. IX+932).—These are annual reviews of the literature on pathology in continuation of the series previously noted (E. S. R., 19, p. 1180). As in previous issues, extensive classified bibliographies and author and subject indexes are included.

Results of investigations in the field of general pathology and pathological anatomy of man and animals, edited by O. Lubarsch and R. Oster tag (Ergeb. Allg. Path. Mensch. u. Tiere, 12 (1908), pp. X+891; 13 (1909), 819).—In this supplemental volume a comprehensive review is given of literature published during the years 1906 to 1909 on the general pathology and pathological anatomy of the eye.

Extensive classified bibliographies are included.

Research work.—Diseases of animals, F. Tidswell (Rpt. Govt. Bur. Microbiol. N. S. Wales, 1909, pp. 11-53, dgm. 2).—A discussion of the principles involved in the investigation of infectious diseases is first entered into. Bacterial infections are then taken up and information presented upon tuberculosis, plague, including a tabular report on ecto-parasites collected from rodents in 1909, pseudo-tuberculosis (lymphadenitis) in sheep, bovine mastitis, etc. The protozoan diseases considered include endemic hematuria in cattle, jaundice in lambs, balanitis in sheep, etc. A list is also given of the insects, ticks, etc.,
known to transmit or suspected of transmitting the parasites of various diseases of man and animals.

The sources and modes of infection, C. V. Chapin (New York and London, 1910, pp. IX+399).—According to the author, this work is intended to indicate the principles which should guide sanitary practice, and to point out how laboratory work and epidemiological studies in recent years have modified certain of these principles. Its chapters take up the life of disease germs outside of the body, carriers, and missed cases, limitations to the value of isolation, and infection by contact, fomites, air, food and drink, and insects.

Handbook of physiological methods, R. Tiggesf. (Handb. Physiol. Methodik, 2 (1911), 4. Abl., pp. 378, figs. 117).—This is the fourth part of the second volume of this work, and contains a description of the technique and apparatus utilized in hemodynamics. The main chapters are on hemodynamical measuring and registering instruments (36 figures) and special hemodynamic methods and hemodynamic operations (81 figures).

This work will be of value to those interested in studying the physiology and pathology of the blood and blood stream.

The behavior of the fatty substances in the kidney of the dog, A. Wisskirchen (Über das Verhalten der fettigen Substanzen in der Hundeniere. Inaug. Diss., Univ. Bern, 1909, pp. 19, pl. 1, figs. 2).—The principal object of this work was to determine whether physiological fat was present in the kidneys of normal dogs. Kidneys were examined from 22 normal healthy dogs of various ages, from 21 starving and undernourished dogs, from 3 overnourished and obese dogs, from 22 nephritic (cystic distemper) dogs, and from 42 dogs treated with various poisons (phosphorus, chloridzin, strychnin, potassium bichromate, etc.), and from 3 dogs in which the pancreas had been extirpated.

The results of the work show that the kidneys of all normal dogs contain fat in the cells of the medullary rays (newborn or young animals have the fat of the kidneys lodged in the basal portion of the cells of the ductus papillares). In the dogs which had starved for a long period or where little fat was given in the food, the fat in the medullary rays diminished partly or completely. On the other hand, the kidneys of the overnourished and obese animals showed fatty infiltration in the loops of Henle and the contorted tubules. In the poisoned dogs the lesions were either diffuse or focal, but in all instances the initial degenerative process began in the medullary rays and in the contorted tubules.

A suggestion for a simple expression of the value of a specific serum, Lentz (Ztschr. Immunitätsf. u. Expt. Ther., II, Ref., 3 (1910), No. 7, p. 797).—The author suggests expressing the results of a serological test in the form of a fraction. When determining the agglutination of a certain bacterial strain with a definite amount of serum, the numerator represents the value found, and the denominator the titer of the serum.

In regard to the existence of a diastatic leucocyte ferment, L. Haberlandt (Pflüger's Arch. Physiol., 132 (1910), No. 1-4, pp. 175-204, pl. 1).—The results point to the view that the diastatic ferment which exists in blood serum is partly of leucocytic origin.

In regard to the splitting off of the bacteriolytic immune body, W. Spät (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 7 (1910), No. 6, pp. 712-720).—The immune body bound to the cholera vibrio can be split off and can be conveyed to other fluids. These fluids then give the same reactions which were previously possessed by the original serum, even after heating. The activity of the extract is greatest when the sensitization of the bacteria is made with an inactive serum.
Secondary and tertiary cholera substances are capable of binding immune substances; cholera-precipitates, on the other hand, do not possess any binding capacity for normal serum.

The cause of natural immunity in pneumonia, E. Unger mann (Arb. K. Gesundbatt., 36 (1911), No. 3, pp. 341–357). — It is concluded that normal resistance against pneumonia is due to the phagocytic power of the fresh normal serum.

From the results it is noted that after a single infection the blood serum is so changed that in conjunction with the antigen it inhibits hemolysis. Furthermore, it is seen that it is possible with the method to differentiate the individual members of the septicemia group.

Treatment of Purpura hemorrhagica with streptolytic serum, J. J. Joy (Amer. Vet. Rev., 38 (1911), No. 4, pp. 539, 540). — The author with 30 cases of this condition and serum had quicker and cleaner recoveries than with the old line treatment. The histories of 3 cases are appended.

Differentiation of the meningococcus from similar organisms by the peritoneal test, C. Dopter (Compt. Rend. Soc. Biol. [Paris], 69 (1910), No. 38, pp. 600–602). — The test is based on the reaction of Pfeiffer, and was made with the true meningococcus, the pseudomeningococcus, and the gonococcus.

The action of spermotoxins upon the female organism and the egg, M. P. Tushnov (Üchen, Zap. Kazan, Vet. Inst., 27 (1910), No. 1, pp. 29–31; abs. in Ztschr. Immunitätsf. u. Exp. Ther., 11, Ref., 3 (1910), No. 7, p. 820). — The author reports the fact that he was able to immunize actively rabbits with sperma-spermotoxin, and thus produce sterility.

Clinical results with bacterial vaccine, F. E. Barnes (Amer. Vet. Rev., 33 (1910), No. 3, pp. 392, 393). — A report of 10 cases, among which were polo evil, quitter, and fistula, and which were successfully treated with antisuppurative bacterial vaccine.

The action of Bacillus coli on the animal organism, J. Studzinski (Compt. Rend. Soc. Biol. [Paris], 70 (1911), No. 7, pp. 225–227). — In this preliminary note the author states that after giving B. coli subcutaneously, intravenously, intraperitoneally, and per buccal cavity, lesions could be noted in the liver and kidneys. The gross and microscopic characteristics are stated in detail.

Investigations in regard to the serum of sheep infected with the Preisz-Nocard bacillus and that of cachetic horses, G. Finzi (Compt. Rend. Soc. Biol. [Paris], 69 (1910), No. 25, pp. 64–66; abs. in Ztschr. Immunitätsf. u. Exp. Ther., 11, Ref., 3 (1910), No. 3, p. 399). — The antityptic property in the serum of a sheep infected with the Preisz-Nocard bacillus is almost always uniformly diminished, and where caseous suppuration exists the antityptic index is always lower. No benefit therefore can be expected by noting the variations in the hemolytic capacity of the serum for detecting tuberculinosis.

caseous suppuration, or scours, because the variations are not characteristic of any disease.

Anthrax, with special reference to its suppression, H. J. Washburn (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 217-228, pls. 3; Farmers' Bul. 439, pp. 16).—This paper discusses the nature and history of the disease, the forms of anthrax, the anthrax bacillus, methods of combating infectious diseases, vaccination as a preventive, and other preventive measures.

The vaccination of bovines against symptomatic anthrax in Switzerland and other countries, R. Balavone (Schweiz. Arch. Tierheilk., 51 (1909), No. 3, pp. 137-185, figs. 7; abs. in Berlin. Tierärztl. Wochenr., 26 (1910), No. 52, p. 1053).—After describing the various vaccinating methods and substances, the author discusses the results obtained up to date in the Cantons of Bern, Waadt, Freiburg, Glarus, and Graubünden in Switzerland, and, further, in Baden and Bavaria in Germany, and in the United States. From the results obtained the author concludes that much danger is connected with the vaccination against symptomatic anthrax, and recommends that when vaccination is done it should always be accompanied with an insurance against the loss of the animal. Such is the case in the Canton of Bern.

A report on the outbreaks of aphthous fever in Pennsylvania in 1908-9, L. Pearson (Ann. Rpt. Penn. Dept. Agr., 15 (1909), pp. 181-247, pls. 14, map 1).—This is a detailed account of the work conducted by the State of Pennsylvania during the outbreak of foot-and-mouth disease in 1908-9, a report of which by the Bureau of Animal Industry of this Department has been previously noted (E. S. R., 21, p. 383).

Rabies or hydrophobia, J. R. Mohler (U. S. Dept. Agr., Farmers' Bul. 449, pp. 23).—This paper is based upon the article above noted.

The complement binding reaction for diagnosing rabies, W. Nederigailoff and W. Sawtschenko (Ztschr. Immunitätsf. u. Exp. Ther., 1, Orig., 8 (1910), No. 3, pp. 353-357).—A specific rabidical serum yields a complement binding reaction, (1) with the brain substance from rabid and normal animals, and (2) with the salivary glands from man and dog dying as a result of rabies.

No reaction could be obtained with the extracts of the internal organs and muscles from man, dogs, guinea pigs, rabbits, and sheep dying from rabies.

The treatment of rabies in animals, P. Remlinger (Rev. Gén. Méd. Vét., 16 (1910), No. 189, pp. 439-507).—The author, after considering the various methods in use for treating rabies in animals, such as the dog, rabbit, sheep, bovine, and horse, and in man, details some of his results obtained by the simultaneous serum-virus method for animals.

The results show that an excess of virus in the mixture is better than an excess of serum for vaccination.

A study of surra found in an importation of cattle, followed by prompt eradication, J. R. Mohler and W. Thompson (U. S. Dept. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 91-98, pls. 3, figs. 2; Circ. 169, pp. 18-97, pls. 3, figs. 2).—Of 46 bulls, 2 cows, 1 heifer, and 2 calves of 7 different breeds of the so-called Brahman cattle that were introduced into this country from India in June, 1906, 3 were found by injecting the blood into rabbits on July 5 and 6 to be
infected with *Trypanosoma evansi*, the causative agent of surra. The 3 infected animals were destroyed July 20 and the remaining cattle protected from blood-sucking flies and mosquitoes which swarmed around the corral in countless numbers. "On completion of the screening of the south and east sides of the corral an abundant supply of sticky and poisonous fly paper was spread about within the inclosure, and very shortly all the *Tabanus atratus* were caught or destroyed, along with large numbers of the other Tabanidæ and *Stomoxys calcitrans*, one of the Muscidæ. However, a considerable number of the latter species and a few *T. lataula* and *T. costalis* still remained, and it seemed impossible to eliminate them by this temporary screening."

In a second series of inoculations made July 31, 7 animals were found infected and were destroyed. A specially constructed fly-proof stable containing individual fly-proof box stalls was then erected for the purpose of eliminating all kinds of flies, and especially the stable fly, *S. calcitrans*, considered by some authorities as being capable of transmitting trypanosomal infections. "After this second test it seemed plausible to consider that only the Tabanidæ—and probably only the *Tabanus atratus*—were responsible for the spread of the infection, and that the disease would be eradicated with the elimination of those animals which had been infected by these flies previous to July 27, when this *Tabanus* was effectually excluded as a factor in the conveyance of the infection."

Four additional animals were found infected on August 6 and 4 on August 11 and were destroyed, making a total of 18. Further injections of blood resulted negatively and the remaining animals, 33 in number, were released from quarantine on November 4, 1906.

The investigations led the authors to conclude that there were only 3 infected zebus at the time of arrival of the cattle in quarantine and that the others became subsequently infected by means of the plague of flies present in the vicinity of the quarantine station.

The authors discuss the history of the importation of Indian cattle into America, the characteristics of Indian cattle, the nature of the causative agent of surra and the disease which it produces, rabbit experiments with infected blood, and the rôle of the Tabanidæ in the transmission of surra.

"It has been definitely shown that in surra as well as in other trypanosomal infections microscopical examination of either stained or unstained blood films will not suffice in making a diagnosis, and that the only satisfactory results are obtained by animal, particularly rabbit, inoculations."

"Relative to further importations into the United States of any class of susceptible animals from surra-infected countries for agricultural purposes or for menageries or zoological gardens, the experience gained in this outbreak indicates that it would be imprudent to import such possibly infected animals without testing each individual, either before or after arrival, by blood inoculations of susceptible small animals, preferably rabbits."

**The susceptibility of the dog to African horse-sickness, A. Theiler (Jour. Compar. Path. and Ther., 23 (1910), No. 4, pp. 315–325).—**This reply to the account previously noted (E. S. R., 23, p. 391) includes a report of further experiments.

"Of 2 dogs injected subcutaneously with 5 cc. of a filtrate mixture obtained by diluting 1 cc. of virus with 4 cc. water and passing the mixture through a Berkefeld filter both contracted typical horse-sickness reactions, and one died with all the lesions of horse-sickness on post-mortem examination. The blood of the dog which died, tapped during the reaction and 2 cc. injected subcutaneously into a mule, communicated typical horse-sickness of an acute type,
from which the mule died. . . . Of 7 susceptible dogs injected with blood of a dog suffering from horse-sickness, all contracted typical horse-sickness reactions. The dog injected with one-thousandth part of a cubic centimeter recovered from the disease, but the injection of 2 cc. of its blood proved virulent for a horse which died of horse-sickness on the eleventh day."

Note regarding the preceding article, J. McFadyean (Jour. Compar. Path. and Ther., 23 (1910), No. 4, pp. 325-328).—A further discussion of the subject.

Contribution to the biology of the tubercle bacillus and some acid-fast saprophytes, H. Windisch (Beitrag zur Biologie des Tuberkelbacillus und einiger Säurefester Saprophyten. Inaug. Diss., Univ. Bern, 1908, pp. 90).—In this work the author found that the human type of tubercle bacillus when grown in acid bouillon changes its characteristics in so far that it at times reduces the acidity and at other times increases it, but that in most instances the reaction never reaches the neutral point. This manifestation, however, is inconstant, as there are strains which make bouillon alkaline and then go over to acid formation. In a bouillon of the same composition, the human type of bacilli, which were rendered avirulent by passing them through cold-blooded animals, usually made the media alkaline. Bovine tubercle bacilli and the bacilli from cold-blooded animals render the substrat alkaline, and it remains so. Avian tubercle bacilli likewise produce basic substances which render the media less acid; but alkalinity only sets in with these bacteria when a superficial growth is present. The various acid-fast saprophytes examined by the author when grown in an acid medium in most instances produced a strong alkalinity.

The author, on the basis of the above tests, does not believe that the various types of tubercle bacilli can be differentiated from one another by the production of acid or alkali.

Human tuberculosis as a symbiotic double infection, Sophie Fuchs (Ztschr. Tuberkulose, 16 (1919). No. 4, pp. 351-364, figs. 5).—The author, on the basis of C. Spengler's theories (E. S. R., 24, p. 483) in regard to Bacillus humano-longus, shows that tuberculosis in man rests upon a symbiotic double infection which can be proved by the double precipitin reaction, and furthermore by the general behavior of the precipitins in the blood.

The diagnostic and prognostic value of Ehrlich's diazo reaction in pulmonary tuberculosis and its behavior during specific treatment, J. von SzaboKY (Ztschr. Tuberkulose, 17 (1911), No. 2, pp. 105-119).—The author investigated 422 urines, 372 of which came from tuberculous subjects (man), 12 from suspected cases, and 38 from nontuberculous cases. From this work he concludes that the diazo reaction has no value as a diagnostic reagent, but that where it is constantly present in tuberculous subjects it points to a bad prognosis.

A contribution to the ophthalmo-reaction obtained with Bovo-tuberculol D, Abel (Berlin. TierärztL Wehnschr., 27 (1911), No. 14, pp. 236, 237).—Comparative tests between Bovo-tuberculol D (Merck) per conjunctival sac and Koch's tuberculin injected subcutaneously led the author to conclude that the former does present some advantages over the latter.

The precipitin reaction for the diagnosis of tuberculosis, H. Vallee and G. Finzi (Rec. Méd. Vét., 87 (1910), No. 18, pp. 408-413; abs. in Ztschr. Immunitätsf. u. ExpI. Ther., II, Ref., 3 (1910), No. 9, p. 965).—According to the author, the precipitin reaction under certain conditions can be a valuable diagnostic agent for tuberculosis.

Experimental studies in tuberculosis, A. MarkX (Berlin. TierärztL Wehnschr., 27 (1911), No. 7, pp. 115-117).—From these experiments, which deal with the bactericidal properties of sodium oleate for the tubercle bacillus,
the author concludes that this substance is capable of fully destroying the viability of the tubercle bacillus, and that bacteria so killed are very efficient for immunizing purposes.

**Report of the International Commission on the Control of Bovine Tuberculosis** *(U. S. Depl. Agr., Bur. Anim. Indus. Circ. 175, pp. 27).*—This is a detailed report of the various committees of this commission, who conducted investigations in regard to (1) education and legislation, (2) location of tuberculosis in cattle, (3) dissemination of bovine tuberculosis, and (4) disposition of tuberculous animals, together with 15 resolutions adopted by the commission as a whole.

**The occurrence of actinomycosis in cows’ udders,** J. H. Patterson *(Vet. Jour., 67 (1911), No. 431, pp. 269–271).*—In investigations of about 50 specimens of udders (examined within a period of 2 years) suspected of tuberculous lesions, the author found the lesions in 5 of the cases, or an average of 10 per cent, to be due to actinomyces.

Contagious granular vaginitis in cattle, and its relation to sterility and abortion, A. Wilson *(Vet. Jour., 66 (1910) No. 422, pp. 469–482).*—This paper discusses the etiology, symptoms and course, differential diagnosis, therapeutics, sequelae, etc., and reports cases of this disease.

Of 1,800 head of cattle examined by the author within the year, 60 per cent of the females were affected with chronic vaginitis follicularis in varying degree; most of the animals were bred in Essex, while others were brought from different counties to be tested. It is stated that not a single case of the acute disease, as described by European writers, has presented itself.

“Contagious granular vaginitis is to be handled as an infectious disease on the usual lines, disinfection and isolation being essential for its control and eradication. The earlier stages of the malady call for curative and prophylactic measures somewhat similar to those recommended for epizootic abortion. (1) Antiseptic irrigations of all animals, diseased and healthy; (2) cleansing and disinfection of the external genitals, tail, and hind quarters; (3) disinfection of the cowsheds or other infested buildings, especially floors and gutters or channels; (4) isolation of diseased, suspected, or newly arrived animals; (5) cessation from breeding for a reasonable time, 6 to 8 weeks (3 months after abortion). The later or chronic stages do not appear to require any treatment.”

**Eradicating cattle ticks in California,** W. M. Mackellar and G. H. Hart *(U. S. Depl. Agr., Bur. Anim. Indus. Rpt. 1909, pp. 283–300, pl. 1, figs. 4; Circ. 174, pp. 283–300, pl. 1, figs. 4).*—The authors first review the conditions obtaining in California prior to the commencement of eradication work in July, 1906. Upon investigation in that year San Luis Obispo, Santa Barbara, San Diego, Orange, Fresno, and Ventura counties were found to be heavily infested, and Tulare, Kern, Kings, Los Angeles, Riverside, San Bernardino, and Madera counties were found to be infested to a lesser degree.

In discussing the methods used in tick eradication in California, they consider the dipping solution, its preparation and use, and the dipping vats found most practical, namely, the swim vat, cage vat, and wade vat, with detailed illustrated plans for the construction of the first 2. “The dipping season in California begins about April 1 and must continue at 30-day intervals until 8 or 9 dippings have been made in order to clean the range in one season. Dur-
ing these 8 or 9 months it is necessary for the inspector to be present at each dipping and supervise the mixing of the dipping fluid in person." In order to prevent the entrance of infested Mexican livestock, a stock-proof fence is being erected along the international line.

"As a result of 4 years' work by the Bureau and state officials, California has only 9,315 square miles, instead of 69,755 square miles, of territory in quarantine for Texas-fever ticks. Of this area remaining in quarantine a large percentage is at present tick free and should soon be in a condition to be released. Of the original 153,476 cattle infested there remain under local quarantine 41,906. This number includes all herds on which the slightest infestation has been found in 1910, and many of these will no doubt be free with the close of this season's work. Half of this number are on one large ranch where eradication work has been slow on account of its size, the roughness of the range, and lack of cooperation from the owner.

"Prior to the inauguration of tick eradication in California condemnations for Texas fever were numerous in the abattoirs having federal inspection. During the past 2 years not a single condemnation for this disease has occurred in Los Angeles, where the majority of the cattle from the quarantined area are slaughtered. In the past year deaths from Texas fever on the ranges, where some years back losses annually reached into the thousands of head, have been so few as to be hardly worthy of notice. Our experience has proved that tick eradication is not only possible but with stringent laws and proper methods is very practicable. When attained it returns to the individual owner and the cattle industry at large many times more than the cost of its accomplishment."

Woody aster (Xyloorrhiza parryi), O. L. Prien and L. C. Raiford (Wyoming Sta. Bul. 88, pp. 3-29, pgs. 4).—This bulletin records information collected which indicates that the woody aster is the cause of serious loss of sheep in Wyoming. This plant grows only on alkalied gumbo-clay soils and, except for one recorded season, is always heavily infested with a fungus (Puccinia xylorrhiza) which may add to the poisonous character of the plant.

Aster poisoning is characterized by lassitude, difficult respiration, muscular weakness, bloat, and final prostration. From 90 to 100 per cent of the animals affected die. The duration of the illness is from a few hours to several days. Gastro-enteritis results from fermentation of ingesta acting as an irritant; a general passive congestion is due to weak and impeded heart action, and in part by reason of diaphragmatic pressure on the lungs produced by tympany. There is an albuminoid degeneration of the liver and kidneys due to the precipitation of proteids by a toxin or toxins. The treatment is purely symptomatic and is not uniformly successful. It consists in the administration of stimulants in small doses, carminatives, and antimonials.

The results of feeding-pen experiments are reported as follows: "Although purged, and fasted for a day, before placing in the feeding pens, the sheep persistently refrained from eating the growing plant other than in a few instances. After nibbling of it slightly they would exhibit considerable lassitude and dejection and thereafter avoid it entirely. A young ewe, taken from the reserve and penned May 22, ate of the aster somewhat on May 23 and again on May 24 and on the morning of May 25 was found dead. An old wether, placed in the feeding pen May 31, after the usual preparation, avoided eating the plant for a time, but finally ate of it freely, dying June 2. . . ."

"A young ewe and an old wether, both freshly penned June 11, were given small amounts of the dried plant on June 15. They were allowed to eat as freely of it as they wished on June 16 and 17 and they did seem to relish it more than had been the case with the growing plant. On June 17 the young
Immunization of goats against Malta fever, H. Vincent and Collignon (Compt. Rend., Soc. Biol. [Paris], 69 (1910), No. 3, pp. 468-470).—Results of tests with the vaccine prepared by the author (by taking an emulsion in physiological salt solution, of a 3-day-old gelatin culture of Micrococcus melitensis and treating it with ether and agitating, then evaporating off the ether and heating at 38° C.) on young goats are reported. The results obtained were considered good.

Some recent experiments on infectious anemia of the horse, M. Francis and R. P. Maesteller (Amer. Vct. Rev., 39 (1911), No. 2, pp. 132-147).—This is a report of studies conducted in continuation of those reported in Bulletin 119 of the Texas Station, previously noted (E. S. R., 20, p. 1084).

A horse, which was kept for 2 years in a small pasture with several infected horses and mules, did not become infected, although it ate from the same manger, drank from the same trough, and grazed with them. At the end of 2 years the horse was injected with 3 cc. of blood from an infected mule, a high fever developing on the twelfth day and again on the twenty-third day, which proved fatal.

In a second experiment 4 oz. of blood drawn from the jugular vein of the horse mentioned above and given by mouth to a healthy horse on November 26 produced the disease but did not prove fatal. Four oz. of blood drawn on January 16 from the animal infected November 26 just at the close of the fifth reaction and injected into a healthy horse caused its death on April 10. Four oz. of blood from the horse which died April 10 was given by mouth on March 25 to another horse but failed to infect.

In a third experiment large numbers of larvae of the cattle tick (Margaropus [Boophilus] annulatus), the progeny of females which engorged on an infected horse, were applied and attached to an uninfected horse but failed to produce the disease. In a fourth experiment bisulphate of quinin administered by mouth to a 10-year-old mule appeared to arrest the fever. In a fifth experiment atoxyl was administered but failed to be of value. In a sixth experiment a 12-year-old mare that was subcutaneously inoculated with 15 cc. of porcelain-filtered blood from a mule the blood of which was known to be virulent, developed the disease; trypanblue was then injected intravenously but apparently had no value as a curative agent. In the seventh and last experiment here reported the intravenous injection of trypanblue failed to arrest the disease.

Temperature tables accompany the reports.

Observations on bursatti [summer or rain sore], C. L. Roadhouse (Amer. Vct. Rev., 38 (1910), No. 3, pp. 376-382).—The author, after detailing his clinical findings with this disease, concludes "that he was successful in treating bursatti by excising the diseased tissues as completely as possible, followed by the application of antiseptic solutions and dusting powders; that strong solutions of formaldehyde prove effective in checking the secretions and excessive granulations, without noticeable ill effects to the animal; and that animals suffering with the extensive forms of the disease can be treated more successfully by removing them to cool climates where the disease is not apt to recur." In no case were flaria found in the blood.

Observations upon equine colic, P. Speiser (Münch. Tierärztl. Wochenschr., 55 (1911), No. 6, pp. 87-89; abs. in Vct. Rev., 23 (1911), No. 1190, p. 696).—Among 65 colic cases treated by the author during the year were 6 fatal cases of verminous embolism of the colic arteries caused by Strongylus armatus.
In one case death occurred after 3 days, while the other 5 extended over periods of from 16 to 23 days.

Investigations of equine piroplasmosis in the Government of Ryazan in 1908, A. W. Belitzer (Ztschr. Infektionskrank. u. Hyg. Haustiere, 7 (1910), No. 3–4, pp. 214–233; abs. in Jour. Trop. Vet. Sci., 5 (1910), No. 3, pp. 624–628).—The outbreak of this disease in 1908 first occurred on May 11, the greatest number of cases appearing from May 19 to 24. "Out of 115 animals attacked 88.5 per cent were imported from the steppes and only 10.5 per cent locally bred. Of the former 58 per cent were attacked in their first year, 34 per cent in their second year, and 7 per cent in their third year after importation." A complication with colic was observed in 108 of 115 sick horses. The virulence of the outbreak, which has been found to be variable in former years, was as great at the beginning of 1908 as at the end.

"In the treatment considerable success followed intramuscular injections of perchlorid of mercury alternated with 5 gm. doses of calomel in ball. Five tenth gm. doses of atoxyl subcutaneously also appear to act satisfactorily together with salicylate of mercury in 0.5 gm. doses in ball."

Dermacentor reticulatus appears to transmit the disease in the northern part of Russia and Hylonomma aegyptium in the southern part.

The treatment of piroplasmosis of horses, A. W. Belitzer (Abs. in Bul. Inst. Pasteur, 9 (1911), No. 5, p. 218).—Two horses experimentally inoculated with the virus, and injected with trypanblue, 1 receiving 4 injections and the other 5 injections of 100 cc. of a 1 per cent solution, were not infected while the check animal succumbed to a grave form of the disease.

Poultry diseases and their treatment, R. Pearl, F. M. Surface, and M. R. Curtiss (Maine Sta. Doc. 398, pp. IX +216, figs. 49).—This is a compilation and digest of information regarding the commoner diseases of poultry, their diagnosis, etiology, treatment, and prognosis.

The nematodes parasitic in the alimentary tract of cattle, sheep, and other ruminants, B. H. Ransom (U. S. Dept. Agr., Bur. Anim. Indus, Bul. 127, pp. 132, figs. 152).—In this paper the author describes the various species of nematodes occurring in the alimentary tract of ruminants in detail for purposes of comparison. Illustrations showing the characteristics accompany the descriptions of the more important species. About 50 species which have been reported as parasitic in the alimentary tract of ruminants are listed, not less than 30 of these being known to occur in this country.

The methods of collecting and preparing specimens and the structure of nematodes parasitic in the alimentary tract of ruminants are first dealt with. The greater part of the work is taken up by keys to and descriptions of the families, genera, and species. Under each species the author gives the synonymy, specific diagnosis, hosts, location, locality collected, life history, and means of control, so far as known. The work concludes with a compendium of species arranged according to hosts.

Pulmonary distomiasis, H. Hanson (Abs. in Amer. Vet. Rev., 39 (1911), No. 3, pp. 314, 315).—The occurrence of the lung fluke (Paragonimus westermanii) in cats at Milwaukee, Wis., is reported. Three other reports of the occurrence of this parasite in the United States are mentioned, namely, in hogs at Cincinnati, Ohio, in cats at Ann Arbor, Mich., and in dogs at Columbus, Ohio.

The pharmacology of sulphur and its compounds, Wild (Merck's Rpt., 20 (1911), No. 3, p. 61).—A discussion in regard to the various uses of sulphur in medicine. A comparison is made with other drugs used for some of the same purposes.

\[4496^\circ\]—No. 4—11——7
RURAL ECONOMICS.

Recent immigrants in agriculture, A. E. Cance (Washington: Govt., 1911, pp. 75).—This is an abstract of the report of the Immigration Commission on recent immigrants in agriculture in the United States which shows the scope, method, and purpose of the investigation, a general sociological and economic survey of the immigrants in rural communities, the different races in agriculture, their conditions of employment, housing conditions, standard of living, etc.

Immigrant rural communities, A. E. Cance (Survey, 25 (1911), No. 15, pp. 587-595).—The author, who was in charge of the report issued by the Immigration Commission in 1910 relative to recent immigrants engaging in agriculture in the United States (see above), discusses at length the history, economic characteristics, social progress, and institutions of the rural immigrant in the United States.

It is pointed out that about one-fourth of all male breadwinners of foreign parentage were engaged in agricultural pursuits in 1900, although a greater part of them were of the older immigration who settled in the Middle West years ago and who have now become thoroughly Americanized and have made successful and prosperous farmers. In the East and South, where the foreign rural groups are new, infrequent, and unsettled, they have yet to prove their fitness generally for agricultural pursuits.

It is shown that the immigrant as a farmer or permanent farm laborer generally becomes a real economic factor in rural pursuits, but as a seasonal agricultural laborer—that is, one who lives in the city during the winter and works on the farm for only a few months during the summer, usually in the fruit and vegetable districts—he amounts to no more than a casual economic interest to the community.

The author directs most attention to the south Italians and gives illustrations of where particular groups of them have settled in Louisiana, Texas, North Carolina, New Jersey, New York, and Rhode Island. Each family has purchased a few acres of land, which, as a rule, had been deserted by Americans or had never been brought under cultivation, and by reason of their specialization, intensive farming, and cooperative marketing, their returns have been fairly remunerative. “The hundreds of little berry farms, vineyards, or sweet potato or pepper fields which make these Italian communities real oases in a waste of sand and lowland, bear unmistakable testimony to the ability of the much-maligned south Italian to create wealth and to make progress materially, morally, and politically under rural conditions.”

An important economic feature is illustrated by a cooperative marketing association at Independence, La. Whereas individual growers formerly shipped their berries to commission merchants in Chicago and neighboring cities with unsatisfactory and sometimes ruinous results, the berries are now sold to platform buyers f. o. b. Independence with gratifying results. “During the spring of 1910 the association sold $357,639 worth of berries for its members.”

It is found that the Hebrew is not adapted by training or tradition to become a pioneer farmer, and his success is confined to those who have been farmers abroad or have had successful training or experience in the United States previous to permanent settlement.

Small holdings (Bd. Agr. and Fisheries [London], Ann. Rpt. Proc. Small Hold. and Allot. Act [etc.], 1910, pp. 71).—The Board of Agriculture and Fisheries, in making its report for 1910 relative to the administration of the small holdings and allotments act, shows that while it has experienced some difficulty in the administration of the work, considerable progress has been made during the past year in satisfying the demand for small holdings.
On December 31, 1910, 89,253 acres had been actually acquired or agreed to be acquired for small holdings by county councils in England and Wales, of which 53,642 acres had been purchased for £1,695,836 and 35,611 acres leased for rents amounting to £44,489. Of this land 65,923 acres had been actually let to 4,846 individual small holders, and 52 acres sold to 7 small holders. It is regarded as significant that such a small percentage of the applicants desired to purchase holdings.

In addition to the text, tables are given showing in detail the work of the board regarding applications for small holdings, rents, loans or other advances, compulsory orders, voluntary schemes, etc.

The Burwell small holdings after four years of tenancy, J. H. Diggle (Jour. Bd. Agr. [London], 18 (1911), No. 1, pp. 1-9).—This article reports the progress made during 4 years' tenancy and reviews the work with special regard to the employment of labor, the productivity of the soil, the output of stock and produce, and the economic result generally of the conversion of a large Cambridgeshire estate into small holdings and allotments.

It is shown that the estate contained 917 acres and was let to 80 tenants in 1906. Previous to that time it was formed at a loss. Now it is self-supporting and a margin is available to meet the cost of small improvements and progressive equipment. The following returns indicate the success of the tenants since the division of the estate and their entry on the land:

Census of live stock on the Cambridgeshire estate.

Other tables are given illustrating the progress of the tenants in several ways. "The tenants, satisfied that their tenure is secure, and holding the land at a moderate rent, are encouraged to put their best into their work, and thus to reap the reward of their thrift and personal labor."

Cooperative agricultural societies in the United Kingdom (Bd. Trade Labour Gaz., 19 (1911), No. 1, pp. 7, 8).—It is pointed out that the main object of these agricultural societies is to enable the members more efficiently and profitably to carry on their daily occupation as individual farmers and producers, and they are classified as "productive" and "distributive" societies. The "productive" societies are occupied in buying, manufacturing, and selling the produce of individual members, and are confined chiefly to the dairy industry. The "distributive" societies are usually formed for the collective purchase and distribution of the seeds, manures, implements, etc., required by the members, and for the sale of cattle, eggs, poultry, etc., produced by the members.

The membership of the 653 societies in 1909 numbered 85,272 with a total share capital of £221,268. Their loan capital amounted to £232,158, and reserve and insurance funds to £165,161. The sales of the "productive" societies show an increase in 1909 over 1899 of 210.8 per cent and the "distributive" societies an increase of 360.1 per cent. About 66½ per cent of the total increase for the "distributive" societies has taken place in England and Wales, while 84.8 per cent of the increase for the "productive" societies is attributable to societies in Ireland.
Cooperative credit societies in the United Kingdom (Bld. Trade Labour Gaz., 19 (1911), No. 1, p. 30).—Of the 241 credit societies in the United Kingdom in 1900, 222 were in agricultural districts. The following table gives particulars of the societies making returns for the years 1905-1909, inclusive:

### Status of cooperative credit societies in the United Kingdom.

Agricultural cooperation in Bavaria, T. W. Peters (Daily Cons. and Trade Rpts. [U. S.], 15 (1911), No. 121, pp. 833-837).—The report discusses the actual workings of agricultural cooperation in Bavaria and points out that the principal objects are the granting of loans to farmers and investing their money, the storing and selling of farm products and other articles required by members of the agricultural societies, and the buying of farm machinery, fertilizers, implements, etc. The societies created for the purpose of carrying on the work are of 2 forms, one limiting the financial liability of its members to the amount of their shares, the other where each member is responsible with his entire property for the debts of the society.

The central association comprises 2,479 local cooperative loan societies of farmers, 217 dairy societies, and 18 others with a total membership of over 200,000. The total assets of the local societies in the association at the beginning of 1909 amounted to about $71,000,000. Loans to members for the year were $12,138,000, and investments made for members amounted to $5,402,000.

The agricultural storage houses have been found especially useful to small farmers in selling their products and in buying fertilizers, agricultural machinery, building material, etc. Other statistics and data are given relative to the agricultural loan banks, the live-stock associations, and other forms of cooperation among farmers.

Trade unions in Italy in 1909 (Bld. Trade Labour Gaz., 19 (1911), No. 1, pp. 8, 9).—The total membership of trade unions in Italy on January 1, 1909, was 843,811, a decrease of 9.7 per cent as compared with January 1, 1908. Of these, 405,149, or almost one-half of the membership, are connected with agriculture.

[Data on the progress of cattle insurances in France in 1910] (Internat. Inst. Agr. [Rome], Bul. Bur. Econ. and Soc. Intl., 2 (1911), No. 2, pp. 147-149).—This article shows that in spite of the bad weather, the poor quality and high price of crops, and the increased mortality among cattle, a federation of French farmers had a very good financial year in 1910. While they paid out 80 per cent of the amount collected, the advance in capital was the same as the year before.

It is shown that the annual sum collected in 1906 amounted to 4,301.42 francs; in 1907 to 18,032.40 francs; in 1908 to 45,095.65 francs; in 1909 to 84,147.50 francs; and in 1910 to 118,540.25 francs.

Other facts and figures bearing on the rapid progress of the mutual insurance companies against the death of cattle and results from hail storms are also presented and discussed.
Agriculture in New Zealand, M. Murphy (New Zealand. Off. Yearbook 1910, pp. 745-775).—The author calls attention to the superior opportunities for agricultural development in New Zealand by reason of its climate, uniform rainfall, and the fertility of its soil. Data as to various crops, live stock, and other farm products are reported and discussed.

Agricultural statistics in the British possessions, protectorates, etc. (Brit. Trade [Gt. Brit.], Statist. Abs. Brit. Self-Gov. Dominions, Colonies [etc.], 1893-1909, No. 47, pp. 302-321).—Tables showing the acreage in cultivation and the yield of each of the several cereal and root crops in the various British self-governing dominions, crown colonies, possessions, and protectorates in each year from 1895 to 1909, inclusive, are presented.

Annual agricultural statistics (Statist. Agr. Ann. [Paris], 1909, pp. 356).—This is a report of general agricultural statistics and of statistics as to agricultural imports and exports, for the year 1909, in France and various other countries of Europe.

Agricultural statistics for Norway, September 30, 1907, A. N. Kiær (Norges Off. Statist., 5. ser., 1910, No. 199, pp. 155, pls. 3).—This volume reports on the land area of Norway and its application for agricultural purposes, the number and size of farms, crop yields, number and value of farm animals, etc. Several graphical charts with legends in Norwegian and French are included at the close of the volume.

Wages, rent, prices of stock, provisions, etc., highest market prices (Statist. Reg. Cape Good Hope, 1909, pp. 197-203).—These are statistical tables showing the ruling rate of wages among agricultural laborers, together with wages paid to laborers in other occupations in the various localities in the province of the Cape of Good Hope during the year 1909. The average monthly rent of a laborer’s cottage or hut with garden in 25 localities of the province is found to be £1 65s. 4d., and the average monthly rent of a town lodging for a mechanic’s family £2 8s. 10d.

Foreign crops, May, 1911, C. M. Daugherty (U. S. Dept. Agr., Bur. Statist. Circ. 19, pp. 12).—This circular gives data as to condition of crops in foreign countries in May, 1911, together with tables showing total area production, and exports of grain in specified years.

Educational agriculture, J. Main (West. [Kans.] State Norm. School [Bul.], 2 (1910), No. 3, pp. 74, figs. 10).—This is a discussion of the problem of secondary agriculture with a view to the proper fixing of the upper and lower limits of high-school agriculture and thereby largely determining the work of the elementary and higher institutions. The school chosen in the treatment of this subject “is not an agricultural school in any sense or degree other than that in which any high school with a rural environment or a rural constituency should be agricultural.”

The author has divided the subject into 3 parts. Part 1 deals with the limitations of the field as a realm of knowledge. He believes that nature study should be strictly cultural, agriculture strictly economic, and science strictly scientific, and that an agricultural or scientific education which has regard for a child as a future citizen must consider the necessity of all 3 factors. The present strength of the movement for agricultural instruction in the schools is economic, and according to part 2, which deals with organization and is chiefly a psychological study as a means to solving the problem, it is held that educators should put more stress on the moral and racial significance of the reform and thus aid in the idealization of the vocation as it should be idealized.
to be worthy of a place in an educational system. Chapter 3, on "genetic psychology as an aid in organization," consists of an investigation into the development of the human mind from the earliest years until maturity in order to determine the principles which govern in the organization of agriculture in a curriculum. The charts deal with such matters as a high-school course in science and agriculture, an agricultural calendar for a high school covering several years' work, and a high-school course in agriculture and related sciences showing the place of industrial and vocational electives. Part 3 deals with the equipment of the laboratory, plots and grounds, and agricultural literature. Excerpts from the works of many leaders in educational thought are found in almost every chapter.

Reports of Danish agricultural instructors (Bcr. Landbr. Min. Landöko-nom. Konsulentvirk., 21 (1909), No. 2, pp. 228).—The reports of the various instructors employed by the Danish government, directly or indirectly, are given in the volume, and the more interesting and important phases of their educational and inspection work are briefly discussed.

Fundamentals of agriculture, edited by J. E. Halligan (Boston, New York, and Chicago, 1911, pp. XIV+492, figs. 269, tabs. 19).—This is an elementary text-book for which the editor has secured chapters from many different authors, as follows: Means of Promoting Agricultural Life in America, by K. L. Butterfield; The Soil, by A. R. Whitson; Plant Life, by E. A. Bessey; Manures and Fertilizing Materials, by the editor; Farm Crops, by L. Carrier, A. D. Shamel, W. R. Dodson, O. D. Center, H. P. Agee, E. H. Jenkins, the editor, S. E. McClendon, and C. V. Piper, each dealing with some particular crop or group of crops; Trees and the Garden, by C. P. Halligan, L. Carrier, G. E. Stone, and C. A. Keffer; Plant Diseases, by H. R. Fulton; Insects and Birds, by G. W. Herrick, W. Newell, A. L. Quaintance, A. W. Morrill, and E. H. Forbush; Live Stock and Dairying, by E. S. Good, J. E. Wing, C. S. Plumb, D. J. Lambert, F. W. Woll, and the editor; Feeds and Feeding, by the editor and W. H. Dalrymple; Farm Management, by F. W. Card; Farm Machinery, by L. W. Chase; The Disposal of Sewage on the Farm, and Earth Roads, by J. B. Davidson; The Country Home, by the editor; and Truck Gardening, by G. L. Tiebout. Each topic in the book is treated very briefly and all are arranged in such a manner as to secure a logical development of the subject of agriculture.

Text-book of Egyptian agriculture, edited by G. P. Foaden and F. Fletcher (Cairo: Gort., 1910, vol. 2, pp. VI+321-878, pls. 11).—This is the second volume of the text-book issued by the Egyptian ministry of education (E. S. R., 21, p. 91). It contains a chapter each on farm seeds and rotation of crops, by W. Cartwright; a chapter on farm crops, including cotton, by G. P. Foaden; flax and til. cereals, sugar, pulse, fodder, and wet-land crops, by W. Cartwright, and minor crops, by G. Bonaparte; a chapter each on vegetables and fruits, by G. Bonaparte; a chapter on farm pests, including fungus diseases, by W. L. Balls, and injurious insects, by F. C. Willecocks; a chapter on farm animals, by J. S. McCall; and one on dairying, by W. Cartwright. Six appendixes contain data on crops and areas, census of date palms, exports from Egypt, imports into Egypt, meteorological data, and weights and measures.

A course of practical work in agricultural chemistry for senior students, T. B. Wood (Cambridge, England: School Agr., 1911, pp. 56).—This course of study is the outcome of 17 years' experience in teaching a class of senior students in the University of Cambridge. It has been used for the last 10 years in the form of typewritten sheets, which were given out to the class from day to day and revised from year to year. The course outlines methods of sampling and analyzing soils and plants, of determining nitrogen, phosphoric acid, potash,
limestone, magnesia, sand, humus, and clay, of estimating the plant food values of commercial and farm fertilizers, and of analyzing milk, feeds, oils, and other agricultural products.

Planting and cultivating corn, D. W. Working (W. Va. School Agr., 1 (1911), No. 6, pp. 90-110, figs. 8).— Eight lessons are outlined on the planting and cultivating of corn. Each lesson is accompanied by a laboratory exercise and one or more references to helpful literature.

Suggested course of study in nature-study-agriculture for the one-room rural schools of Illinois (School News and Pract. Ed., 24 (1911), No. 10, pp. 445-452).—This course was prepared by a committee appointed for the purpose at the first nature-study-agriculture conference at the University of Illinois, in March, 1910. It is arranged by months for the 8 years of the elementary school.

School and home gardening, S. C. Kelleher and N. H. Foreman ([Philippine] Bur. Ed. Bul. 31. 1910, pp. 45, figs. 8, pls. 14).—Gardening, as outlined in this bulletin, is prescribed for all elementary schools in the Islands. The authors discuss the objects of school gardening, the divisions of the work into school and home gardens, plant nurseries, and flower and ornamental plant culture, give detailed instructions for selecting a site, fencing, planting, and plating the entire garden, preparing the soil, planning and mapping the pupil's plot, choosing plants and seeds, keeping a record, use and care of tools, transplanting, time of planting, care of plants, disposition of products, and the germinating bed, directions for growing some of the common garden vegetables, procuring seed for the next crop, keeping seeds until planting time, for doing work at barrio schools, decorative gardening, and tree planting. A plan of an individual garden is suggested, and a report on school-garden work in Union Province including the object, local interest, and progress of gardening in the province, together with the details of the supervisor's method of conducting gardening for primary schools, is given.

Arbor day, R. H. Schauteller (New York, 1909, pp. XIX+360).—This is a collection of essays and other articles, exercises, and poems concerning Arbor Day and its history, observance, and significance, together with similar contributions on spring, trees, flowers, and conservation.

Equipment for teaching domestic science, Helen Kinne (New York: Teachers Col., 1910, pp. 100, pl. 1, figs. 63).—The author discusses the problems that are met in planning a domestic science equipment for cookery, table setting and service, housework, laundering and home nursing, suggests practical solutions that have been worked out through experience, and gives a description of what is done in some of the schools and colleges of this country. A chapter each is devoted to the planning for rooms in a new building and the refitting of rooms used for other purposes, the cooking laboratory, the dining room, laundry and equipment for home nursing, the purchase and care of equipment, the total cost of equipment, the cost of maintenance, and the household arts building, Teachers College, Columbia University.

Federal legislation, regulations, and rulings affecting agricultural colleges and experiment stations (U. S. Dept. Agr., Office Exp. Stats. Circ. 111, pp. 24).—This is a revision of Circular 68 (U. S. R., 18, p. 688), including statements concerning the classification of station accounts and the requirements of experiment station accounting.

MISCELLANEOUS.

contains a report of the Chief of the Bureau for the fiscal year ended June 30, 1909, numerous articles abstracted elsewhere in this issue, and a list of the publications of the Bureau during 1909. An appendix contains the rules and regulations of the Secretary of Agriculture relating to animal industry issued during 1909.

Annual Report of Hawaii Station, 1910 (Hawaii Sta. Rpt. 1910, pp. 64, pls. 8, figs. 4).—This contains the organization list, a summary by the special agent in charge as to the investigations of the year, and reports by the entomologist, horticulturist, chemist, and agronomist. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Twenty-second Annual Report of Maryland Station, 1909 (Maryland Sta. Rpt. 1909, pp. XXXV1+306, figs. 96).—This contains the organization list, a report by the director on the work and expenditures of the station, a financial statement for the fiscal year ended June 30, 1909, and reprints of Bulletins 129–136.

Twenty-third Annual Report of Maryland Station, 1910 (Maryland Sta. Rpt. 1910, pp. XXIV+326, figs. 107).—Data corresponding to the above are presented for the fiscal year ended June 30, 1910, the bulletins reprinted being Nos. 137–145, previously noted.

Twenty-first and Twenty-second Reports of New Hampshire Station, 1909–10 (New Hampshire Sta. Bul. 151, pp. 72).—This contains the organization list; a report of the director for the biennial period ended October 31, 1910; financial statements for the fiscal years ended June 30, 1909, and June 30, 1910; departmental reports, the experimental work of which is abstracted elsewhere in this issue; a list of the publications of the station from 1888 to 1908; and meteorological data abstracted on page 316 of this issue.

Twenty-third Annual Report of Rhode Island Station, 1910 (Rhode Island Sta. Rpt. 1910, pp. 349–395+VIII).—This contains the organization list, a report of the director on the work of the station during the year, including a summary of meteorological observations of the year abstracted on page 316 of this issue, and a financial statement for the fiscal year ended June 30, 1910.

Experiment Station Work, LXIII (U. S. Dept. Agr., Farmers’ Bul. 431, pp. 24, figs. 6).—This number contains articles on the following subjects: Sterilizing tobacco-plant beds, conditions essential to clover growing, curing clover hay, the velvet bean, quality and conformation of draft horses, and care of brood mares and newborn foals.

NOTES.

Arkansas University and Station.—New members of the board of trustees include H. B. McKenzie of Prescott, C. C. Reid of Little Rock, Arthur Turner of Jonesboro, and Edgar Brewster of Pine Bluff. W. H. Cravens has been appointed secretary to the board to succeed J. E. Neelly, and J. Walker treasurer. Paul Hayhurst, assistant entomologist, has been appointed professor of entomology and entomologist.

University of California.—The division of agricultural education has begun the publication of The Junior Agriculturist, a semimonthly leaflet for boys’ and girls’ clubs.

Colorado College and Station.—T. J. Ehrhart of Centreville, and Charles Pearson of Durango, have been appointed to the board of control, vice E. H. Grubb and B. F. Rockafellow.

The station is giving increased attention to irrigation and drainage problems, including irrigation investigations in cooperation with this Office. Considerable irrigation engineering apparatus has been acquired for the work.

The station now has five field men located in various sections of the State giving their time to the special agricultural interests, such as fruit growing, insect pests, dry farming, potato growing, etc. These men cooperate with the farmers in carrying on the investigations, hold meetings for the benefit of the farming communities, write articles for agricultural journals, and otherwise render service to communities where their work is carried on.

Connecticut Storrs Station.—Dr. J. N. Currie has been appointed chemist of the cheese investigations.

Georgia College.—L. E. Rast has been appointed instructor in agronomy.

Idaho University and Station.—D. W. Clark of Pocatello has been appointed a member of the governing board in place of O. E. McCutcheon. F. L. Kennard has succeeded O. M. Osborne as assistant agronomist in the station, and Karl J. Thelge has been appointed assistant bacteriologist. E. J. Iddings has assumed the duties of animal husbandman in the station and professor of animal husbandry in the college.

Iowa College and Station.—A four-year course in agricultural education has been added to the division of agriculture for the purpose of training teachers for agriculture and domestic science work in the secondary schools. The recent legislature authorized the establishment of departments in agriculture and home economics in 40 high schools and allotted $500 as special State aid to each of these schools. It is stated that much difficulty is at present being experienced in obtaining competent instructors along these lines and that the establishment of the course is in recognition of the demand upon agricultural colleges for teachers especially trained for the secondary schools. At the present time comparatively few of the agricultural graduates of the college enter teaching work, not over 10 per cent of the last class of 78 contemplating it. A. V. Storm has been appointed head of the new department.

Recent appointments include Miss Winnifred S. Gettemy, of the Illinois Woman’s College, as professor of applied design in the home economics course; B. W. Hammer, of the Wisconsin State Hygienic Laboratory, as dairy bacteri-
ologists, vice John H. Gordon, resigned to engage in commercial work; and F. W. Beckman, a newspaper writer of the State, as editor of the college and station publications.

Kentucky Station.—Recent appointments include J. H. Kastle as research chemist, H. H. Jewett and H. R. Nswenger as assistant entomologists and botanists, and L. S. Corbett as assistant in animal husbandry.

Massachusetts College and Station.—The trustees have voted to dissolve the relationship with Boston University by which the college has, since 1875, constituted the college of agriculture of the university. Plans were adopted for the formal conveyance of the property of the college to the State in accordance with a recent state law declaring the college a State institution. It was also decided to charge tuition to students in the winter courses and to nonresidents of the State who enter the regular four-year course after 1912.

A total of 17 new appointments to the faculty has been announced. Among these are Robert J. Sprague, of the University of Minnesota, as head of the division of the humanities and professor of economics and sociology; Edward M. Lewis as assistant professor of English and assistant dean; Frederick L. Yeaw, of the California Station, as assistant professor in market gardening, vice Charles S. Heller, resigned; Dr. George E. Gage, of the Maryland Station, as assistant professor of animal pathology; Arthur K. Harrison as instructor in landscape gardening, vice John Noyes, resigned; Elvin L. Quaife as instructor in animal husbandry; Frederick A. McLaughlin, a 1911 graduate of the college, as assistant in botany; Herbert J. Baker, also a 1911 graduate, as assistant in the department of agronomy and secretary to the director of the station; and R. W. Ruprecht as assistant chemist in the feed and fertilizer inspection department in the station.

The chemical department of the college has been reorganized under the direction of Dr. J. B. Lindsey of the station, with Dr. Charles Wellington as professor of analytical chemistry and Dr. Charles A. Peters, formerly of the University of Idaho, as professor of inorganic and soil chemistry.

Michigan College and Station.—John W. Beaumont and Jason Woodman have been appointed to the governing board, vice W. L. Carpenter and W. J. Obergdorffer, taking office January 1, 1912. George Bouyoucos, Ph. D., has been appointed research assistant in soil physics, and F. Hasserlink van Suchtelen, Ph. D., research assistant in bacteriology. A soil house has been constructed for the soil investigations conducted under the Adams Act, and a piggery has been completed for the manufacture of the Dorset-Niles hog cholera serum. An addition to the chemical laboratory is in process of erection.

Minnesota University and Station.—Minnesota Farm Review announces the appointment of R. M. Washburn, of the Vermont University and Station, as associate professor of dairy husbandry and dairy husbandman, who entered upon his duties September 1.

Missouri University and Station.—J. A. Ferguson, assistant professor of forestry and forester in the Pennsylvania College and Station, has been appointed professor of forestry. The college owns 50,000 acres of forest land in south Missouri, and these will be utilized in connection with the forestry instruction.

A. J. Meyers, of Howell, Mich., has been appointed superintendent of the short winter courses and assistant to the dean, with the rank of assistant professor. Other appointments include the following assistants: E. G. Woodward and W. W. Wobus in dairy husbandry, the latter vice E. G. Maxwell, resigned; W. E. J. Edwards, a graduate of the Ontario Agricultural College, in animal husbandry; J. P. Dunn and E. C. Hall in the state soil survey work; C. A. Le Clair in agronomy; E. E. Vanatta in agricultural chemistry in the station; and O. R. Johnson in farm management. Walter E. Camp has been appointed
research assistant in veterinary science in connection with the Adams fund project on the investigation of immunity to hog cholera. P. L. Gainey has been appointed instructor in botany. E. S. Vanatta has resigned as assistant in the state soil survey to accept a position with the Bureau of Soils of this Department.

Montana Station.—D. C. Cochrane, assistant in animal nutrition in the Pennsylvania Institute of Animal Nutrition, has been appointed assistant chemist and entered upon his duties August 1.

New Hampshire College and Station.—Fred Rasmussen has resigned as professor of dairying in the college and dairyman in the station to become professor of dairy husbandry at the Nebraska University and dairyman at the Nebraska Station September 1. Vice A. L. Haecker, resigned.

New Jersey Stations.—The horse barn, dairy barn, two silos, and several smaller structures were destroyed by fire July 11, causing a loss of about $25,000. A considerable supply of hay and grain was consumed, but the live stock was saved. The loss was covered by insurance and the work of rebuilding is already under way. It is expected that concrete structures will be erected.

J. G. Lipman has been appointed director of the stations. Miner S. Macomber has resigned as assistant chemist in the State Station and has been succeeded by Willis H. Pearson.

New York State Station.—J. F. Barker, assistant professor of soils in the Iowa College, has accepted a position as soils expert, and began his duties in July. W. H. Alderman, associate horticulturist, has accepted the professorship of horticulture at West Virginia University. He has been succeeded by Richard Wellington, formerly assistant horticulturist, and who in turn is succeeded by Charles B. Tubergen, a 1911 graduate of the Michigan College.

Ohio University and Station.—Prof. Alfred Vivian has been designated acting dean of the college of agriculture for the coming year during the absence of Dean Price in Europe. Ernest D. Waid, assistant professor in agronomy, has resigned to accept a position with the agricultural extension department of the Massachusetts College.

An appropriation of $7,500 was made by the recent legislature to establish a poultry plant.

A country church conference was held at the university July 25-28. The morning sessions were given over to lectures on farm crops, soil fertility, and horticulture, and the afternoon and evening sessions to the discussion of economic, sociological, and religious topics.

The State appropriations to the station for the biennial period 1911-12 aggregate $396,590. Of this $25,000 is for administration, $33,685 for agronomy, $40,000 for animal husbandry, $17,000 for botany, $58,000 for extension work, $23,000 for entomology, $19,400 for forestry, $37,000 for soil investigations, $8,000 for chemistry, $31,000 for horticulture, $15,000 for nutrition, $17,200 for dairying, $34,750 for new buildings, equipment, etc., and $6,355 for the purchase of land.

Recent appointments at the station include J. G. Humphrey, M. F. M. Beegle, and J. E. Mensching as assistant chemists, the first-named in connection with the soil investigations and the others in the nutrition investigations. A. C. Whittier, assistant in nutrition investigations, has resigned to engage in commercial work.

Oregon College and Station.—T. D. Beckwith, of the North Dakota College and Station, has been appointed professor of bacteriology and bacteriologist, vice Dr. E. G. Peterson, whose resignation has been previously noted. Dr. H. E. Ewing has been appointed laboratory assistant, and A. L. Lovett field assistant in entomology; F. R. Brown, F. C. Bradford, and F. V. Tooley field
assistants in horticulture; James Speidell instructor in horticulture; George Reiben horticulturist of the Eastern Oregon substation at Union; Leslie Beaty horticulturist at the Hermiston substation; and F. D. Bailey field assistant in botany and plant pathology.

**Porto Rico Station.**—Winthrop V. Tower has resigned as entomologist to accept a position with the Porto Rico Board of Agriculture.

**Rhode Island Station.**—E. F. Southwick, assistant in agronomy, and Miss Elizabeth E. Amison, assistant biologist, have resigned. Fred J. Godlin has been appointed assistant floriculturist in the college and station, vice E. A. Mallette, resigned to take up commercial work.

**South Carolina Station.**—The appointments are announced of W. B. Aull as assistant botanist and F. G. Tarbox, jr., as assistant in agronomy.

**South Dakota Station.**—Fred D. Fromme has succeeded Orlando E. White as assistant in botany.

**Texas Station.**—The resignations are noted of J. W. Carson as assistant to the director and State feed inspector, taking effect September 1, and N. C. Hamner as assistant chemist. B. Youngblood, assistant agriculturist in the Office of Farm Management of this Department, has been appointed director and entered upon his duties August 15.

**Virginia Station.**—W. K. Mallory, assistant dairy husbandman, has resigned to accept an appointment with the Dairy Division of this Department.

**Washington College and Station.**—O. M. Morris has been appointed professor of horticulture and horticulturist, vice W. S. Thornber, whose resignation has been previously noted. George S. Olson has been promoted from assistant chemist to chemist of the station. H. P. Barss, instructor in botany in the college, has been added to the station staff as assistant plant pathologist, half of his time to be devoted to Adams fund projects in plant pathology. E. F. Gaines has been appointed assistant cerealist in the station.

**West Virginia University and Station.**—A school of agriculture and domestic science of secondary grade has been formally organized. For men there is a 4-year course, a short course consisting of 2 winter quarters, and a winter "farmers' course" of about 2 weeks consisting of popular lectures, demonstrations, and exercises for men over 21 years of age. The 4-year course consists of 3 years of 2 quarters each (for the current year extending from September 15, 1911, to March 22, 1912), and 1 year of 3 quarters. During this last year the work in agriculture is elective, and there is also an opportunity to take 3 hours each quarter of electives in other subjects. This course is planned for young men who expect to go back on farms, but it also contains sufficient work in English, mathematics, science, and German (2 years), to admit its graduates to the college of agriculture with only 2 entrance conditions.

In the short course all of the work is in agriculture and related sciences. The work of the first winter is the same for all students, but in the second winter students have the option of a group in dairying, a group in horticulture, and a group in animal husbandry.

For women there is a 3-year course in home economics, each year consisting of 2 terms of 12 weeks each as in the case of the first 3 years of the agricultural course. The regular academic work for women is the same as that for men, but instead of required work in agriculture they take cooking, sewing, hygiene, music, and home management. They may also take work in dairying, farm crops, and plant propagation instead of German in the third year.

J. H. Stewart has resigned as director, to take effect January 1, 1912, and will be succeeded by E. D. Sanderson. David Carleton Neal has been appointed assistant bacteriologist.
Wisconsin University.—A department of veterinary science has been established with Dr. F. B. Hadley as chairman of the department, as well as veterinarian to the station. A small amount of work has been given during the past few years to agricultural students along this line, but this will now be enlarged. The new department has offices, a dispensary, and dissecting and operating rooms in the new live stock pavilion.

K. L. Hatch has been promoted to the associate professorship of agricultural education and extension, and J. C. Halpin to that of poultry husbandry. Other appointments include F. B. Morrison as assistant to the dean and director, A. C. Burrill as assistant in economic entomology, F. J. Kelley as assistant in experimental breeding, T. J. McCarthy as assistant in horticulture, and L. H. Schwartz as assistant in poultry husbandry.

Vocational Agricultural Schools.—The Massachusetts legislature has recently made it possible for a vocational agricultural school to be established by a town or a group of towns formed into a district. If such a school is approved "by the board of education as to organization, control, location, equipment, courses of study, qualifications of teachers, methods of instruction, conditions of admission, employment of pupils, and expenditures of money," the town or district supporting it will be reimbursed by the State to the extent of one-half the maintenance cost which has been paid by local taxation.

Ten thousand dollars was also appropriated for aiding in the establishment of the vocational agricultural departments in selected high schools. These departments are to be subject to the approval of the board of education in all the particulars above cited in connection with the agricultural schools. Towns providing approved departments will be reimbursed to the extent of two-thirds of the amount of salary paid the agricultural instructor. This agricultural instructor must devote himself exclusively to the supervision of agricultural projects, to be carried out by his students chiefly at their homes, and to giving instruction in the various phases of agricultural science required for the successful understanding and prosecution of those subjects.

New Agricultural School in Nebraska.—At the last meeting of the Nebraska legislature a bill was passed providing for a new $100,000 agricultural school. The school is to be known as the Nebraska School of Agriculture and will be under the control and management of the board of regents of the University of Nebraska. It is to be located at Curtis on a 20-acre campus within the city limits and will also own and use for demonstration and other purposes a 413-acre farm. The law provides for (1) one laboratory building, not less than 2 live stock barns, and the necessary sheds, pens, and inclosures, complete, at an estimated cost not to exceed $75,000; (2) furnishings not to exceed $10,000; and (3) necessary equipment, such as farm implements and live stock, $15,000.

Agriculture in Wisconsin Schools.—The Wisconsin laws of 1911 provide for State aid of $250 when a department of agriculture is established in connection with any free high school. If the department extends to three grades below the high school this sum is increased to $350.

Agriculture in North Dakota Schools.—At the recent session of the North Dakota legislature provision was made for the establishment and maintenance of a department of agriculture, manual training, and domestic economy in state high, graded, and consolidated schools. To derive aid to the extent of $2,500, each of these schools must, among other things, employ trained instructors in agriculture, manual training, and domestic science, and have within one mile of the school buildings not less than 10 acres of land suitable for a school garden and purposes of demonstration.
Provision was also made for the establishment of county agricultural and training schools and their joint maintenance by the State and the county wherein they are located. The yearly cost of maintenance of each of these schools is not to exceed $6,000 per year, of which the State pays one-half and the county the remainder.

Appropriations for District Agricultural Schools in Oklahoma.—Under the Oklahoma laws of 1911 the district agricultural schools at Warner, Tishomingo, Broken Arrow, Lawton, and Helena are each to receive state aid to the extent of $17,000 for 1912 and $19,000 for 1913, while the more recently organized school at Goodwell will receive during the same years $11,000 and $13,000 respectively.

Agricultural Education in Canadian Secondary Schools.—By a recent amendment to the regulations for agricultural education in high schools and continuation schools by the Ontario Department of Education, the duties of the teachers of agriculture under the ministers of agriculture and of education, respectively, are now clearly defined.

Local control is in the hands of an advisory agricultural committee composed of 4 members of the school board and 4 other persons who are actively engaged in agricultural pursuits. The agricultural teacher is hereafter to conduct classes not only in the high-school center to which he has been appointed, but at other centers selected by the minister of education on the application of their high-school or continuation-school boards. The minimum length of a school class in agriculture is to be 4 weeks. Shorter classes for farmers are provided under the authority of the minister of agriculture.

The minister of education has appointed Prof. S. B. McCready, of the Ontario Agricultural College, inspector of these classes and director of elementary agricultural education.

Agriculture in Latin America.—The June number of the Bulletin of the Pan American Union announces the inauguration last April of a government agricultural school in the Potopoto Valley at Sopocachi, near La Paz, Bolivia. Augustin Luna Pizarro, a practical agricultural engineer of wide experience and a noted botanist, is director of the institution. It is probable that a veterinary department will be added to this school later.

The National Legislative Assembly of the Republic of Salvador has prescribed the duties and functions of the department of agriculture recently established, as follows: Supervision and inspection of municipal and interdepartmental roads, establishment of produce exchanges, taking of the general agricultural census, collection of taxes on agricultural products, regulation of irrigation of lands, importation of new machinery for the cultivation and improvement of new agricultural products, establishment of fertilizer factories, analysis of lands, development of commerce in general, and the establishment of an information bureau.

</table>
Endowment for agricultural education and research, except from the federal and state governments, has been relatively quite small. This is especially the case in view of the fundamental position of agriculture and the avenue it opens for practical results which find application in everyday life.

Doubtless the aid which the state and national governments have given is responsible in part for this, and the further fact that the institutions devoted to it are mainly state institutions. The appeal has consequently not been made to private beneficence to the extent that it has in other classes of institutions. Agriculture has been regarded as one of the branches which the state and federal governments were taking care of, and until quite recently there has been no very widespread appreciation of any further needs of these institutions. However, private endowment for agricultural instruction commenced many years ago, and while it has not represented in the aggregate a very large amount, it has reflected the intelligent interest of a considerable number of persons.

The propriety of public aid to agriculture found early advocacy in the well-known words of President Washington in his annual message to Congress in 1796 when he said: "It will not be doubted, that, with reference either to individual or national welfare, agriculture is of primary importance. In proportion as nations advance in population and other circumstances of maturity, this truth becomes more apparent and renders the cultivation of the soil more and more an object of public patronage. Institutions for promoting it grow up, supported by the public purse; and to what object can it be dedicated with greater propriety?"

Many years were destined to elapse, however, before the practical realization of these views in public legislation, and in the interval the efforts of individuals, even though isolated and apparently insignificant, supplied numerous object lessons which doubtless paved the way to subsequent public action.

The first bequest for agricultural education in this country appears to have been that of Mr. Benjamin Bussey, of Roxbury, Mass. In a
will signed July 30, 1835, 200 acres of his farm in Roxbury and half of the income of about $300,000 were bequeathed to Harvard College on condition that there should be established on the farm “a course of instruction in practical agriculture, in useful and ornamental gardening, in botany, and in such other branches of natural science as may tend to promote a knowledge of practical agriculture and the various arts subservient thereto.” Because of other conditions in the will the organization of this work was not attempted until 1870, when a considerable additional sum was granted to Harvard College by the Massachusetts Society for Promoting Agriculture “for the support of a laboratory and for experiments in agricultural chemistry to be conducted on the Bussey estate.”

Operations were begun in 1871 under the name of the Bussey Institution, offering undergraduate instruction as a school of agriculture and horticulture, and giving considerable attention to experimental work as well. In 1908 the scope of the institution was changed to that of graduate instruction and research in applied biology, the subjects so far taken up being economic entomology, plant and animal genetics, and comparative pathology.

Another will made at about the same period as the Bussey bequest, and resembling it as regards the active interest manifested in agricultural education by its maker many years before the establishment of any American agricultural school or college, was made public on the death of Mr. Oliver Smith, of Hatfield, Mass., in 1845. This will provided for a number of educational and charitable enterprises, but among others for the establishment in Northampton, Mass., of an agricultural school and “pattern” farm. The fund set aside for this purpose was not made available until a period of sixty years had elapsed, at which time it had accumulated to over three hundred thousand dollars. A secondary institution, known as Smith’s Agricultural School, was opened to over one hundred students in the fall of 1908, and has since been in operation, with courses in agriculture and home economics as a leading feature of its curriculum.

An actual experiment in agricultural education was instituted in the winter of 1850–51 in the establishment of the Oakwood Agricultural Institute at Lancaster, New York. Funds for this enterprise were derived from the sale of two hundred shares of stock subscribed for by five gentlemen from Buffalo. The school was opened in April, 1851, using the buildings and farm of Judge Theodotus Burrell, the originator and promoter of the plan, but in the following winter financial reverses to the stockholders compelled the abandonment of the enterprise.

Three years later came the establishment of the New York State Agricultural College at Ovid. This institution by 1856 had raised
by private contributions $40,000, and thereby became the recipient of a loan of a like amount from the State. A large farm was acquired at Ovid, a building erected to accommodate 150 students, and the doors opened December 5, 1860. The outbreak of the Civil War and other causes led to its suspension in April, 1861, and to its formal close in the following year.

Upon the passage of the original Morrill Act efforts were made to reopen the institution with the aid of a portion of the federal land grant to the State, but without success. Instead the legislature accepted an offer from Mr. Ezra Cornell of $500,000 and 200 acres of land with farm buildings in case the land grant should be devoted to an institution to be located at Ithaca, N. Y. Subsequently Mr. Cornell made an additional gift of $200,000, and the net result was the organization of Cornell University, with its college of agriculture.

The incorporation of the Maryland Agricultural College in 1856 is of interest, as this is the first institution of the sort still in existence to be established by voluntary contributions. Funds to the extent of about $30,000 were secured in this way from about five hundred residents of Maryland and a few nonresidents participating as stockholders. Land and buildings were acquired, and after three years of maintenance as a private enterprise state aid was enlisted.

The history of the Farmers’ High School of Pennsylvania, now the Pennsylvania State College, is not dissimilar. Contributions of 200 acres of land and $25,000, of which $10,000 was pledged by the State Agricultural Society and $10,000 by General James Irvin, and $5,000 bequeathed under the will of Mr. Elliott Cresson, were obtained and a like sum then granted by the state legislature. Subsequently other gifts were made as the condition to additional state aid.

With the passage of the Morrill Act the Federal Government became the chief sponsor of collegiate education in agriculture. The location of the colleges provided for led to much competition among communities, as a result of which many private contributions, mainly in the form of sites and funds for buildings, were made.

Meanwhile the need for experimental work in agriculture had begun to be realized, and in addition to what could be undertaken in a voluntary way by the colleges of agriculture, efforts were put forth to establish research organizations. In Connecticut in particular, following the earnest advocacy in 1873 of Professors Atwater and Johnson, attempts were made for several years to secure an appropriation from the State for the establishment of an experiment station. The project made many warm and enthusiastic friends but, as might have been expected, the great mass of the farmers took little interest in the enterprise. When it had become apparent that it
could not otherwise succeed Mr. Orange Judd, then editor and proprietar of the *American Agriculturist*, offered on his own part $1,000 to begin the undertaking and on the part of the trustees of Wesleyan University the free use of its chemical laboratory. These offers were made on condition that the legislature should appropriate $2,800 per annum for two years for the maintenance of the station.

Small as were these contributions in amount they proved to be the turning point in the scale. An act making the appropriation proposed was passed unanimously and approved July 2, 1875. The organization at Middletown of the first experiment station in this country speedily followed, and in the period provided for so clearly demonstrated the usefulness of the enterprise that the State assumed responsibility for its operation on a permanent basis at New Haven. Other States soon followed the example set by Connecticut, among them Massachusetts, where a similar gift was made in 1878 by Hon. Levi Stockbridge. To these small beginnings may be traced the comprehensive system of experiment station research of to-day.

The Houghton Farm enterprise deserves mention as the only attempt in America to establish an agricultural experiment station through the munificence of a single individual. In 1876 Mr. Lawson Valentine, of New York City, acquired a tract of several hundred acres in Cornwall, Orange County, N. Y., which he soon afterwards planned to utilize for systematic experimentation in agriculture, on the general model of the work of Lawes and Gilbert at Rothamsted. In 1881 Major Henry E. Alvord was placed in charge, with instructions to organize and operate a scientific department devoted to agricultural investigation and experiment. Houghton Farm was conducted along these lines for about five years, the experimental department being maintained at a total cost of nearly $20,000 per annum. Operations were finally ended by the death of Mr. Valentine in 1888.

To Mr. William R. Lockwood, of Norwalk, Conn., belongs the credit for the first considerable permanent endowment of agricultural research in this country. In a will dated January 9, 1894, half of Mr. Lockwood's estate was devised to the Connecticut State Station "to use and apply all the balance or net income in the promotion of agriculture by scientific investigation and experiment, and by diffusing a knowledge of the practical results thereof among the people of the State of Connecticut in such manner as shall be deemed by the board of control or governing body of said institution for the time being, most practicable and generally useful." This bequest now yields an income of about $10,000 a year.

One of the largest bequests for agricultural education has been that of Mr. Benjamin Thompson, a farmer of Durham, N. H. Mr. Thompson died in 1890, leaving practically his entire estate to the
State of New Hampshire for a state college of agriculture, to be located on his farm. The conditions of the will were accepted by the State March 5, 1891, and in consequence the New Hampshire College of Agriculture and the Mechanic Arts, then located in Hanover as a department of Dartmouth College, was removed to Durham. This necessitated the abandonment of an earlier gift by the Hon. John Conant of 360 acres of land at Hanover, which had been used as a college and station farm. The Thompson bequest became available in 1910, when it amounted to nearly $800,000.

The Storrs Agricultural School, now the Connecticut Agricultural College, owes its establishment and present location largely to the gifts of the Storrs family in 1881, a farm of 170 acres and several buildings being given by Mr. Augustus Storrs for the purpose, and Mr. Charles Storrs contributing $6,000. In 1906 a legacy of the late Edwin Gilbert bequeathed to the college a farm at Georgetown, Conn., of about 356 acres with buildings and equipment, for maintenance by the college for the purpose of teaching agriculture, together with $60,000 for caring for the farm and for instruction.

In the same year the University of California was designated as the beneficiary of a bequest by the late M. Theodore Kearney, of Fresno, of an estate of 5,400 acres, valued at about one million dollars. Considerable litigation resulted, but the case was eventually decided in favor of the university, which came into possession of the property in 1910. This munificent gift is to be used by the college of agriculture and the experiment station for agricultural instruction and research, and affords unusual opportunity for experiments of interest to the San Joaquin Valley.

An estate of about $40,000 was bequeathed by Mr. Philip Weiser, of Lander, Wyo., for an agricultural college at that location. A long period of litigation followed as to the location of the land-grant institution, which was eventually decided in favor of the state university at Laramie.

Numerous donations for the introduction of agriculture into the curriculum of private institutions have been reported. An anonymous gift to Columbia University of $15,000 for agricultural education was announced in 1910, and Mr. William Blodgett has given a farm of 750 acres at Fishkill-on-the-Hudson, which it is planned to develop as an agricultural school. Messrs. George and William W. Mathes in 1901 gave $10,000 to Union Academy, Belleville, N. Y., for this purpose, and through the late Mrs. Phoebe Strawn Illinois College, at Jacksonville, received $20,000 and inaugurated with it a course in secondary agriculture. The establishment of a secondary school of agriculture at Lyndonville, Vt., was effected in 1910 through a gift of Mr. Theodore N. Vail, whose great estate in the vicinity
affords the school abundant materials and unusual opportunities for practical work and observation. About 1900 Rev. Francis Goodwin gave the Handicraft Schools of Hartford, Conn., a farm of 75 acres just outside the city for utilization as a school of horticulture. In 1901 a school of practical agriculture was opened at Briarcliff Manor, N. Y., and maintained through contributions of several business men of New York City, notably Mr. R. Fulton Cutting and the late Mr. Abraham S. Hewitt, for two years, when it was closed on account of failure to secure a permanent endowment of $200,000. There have also been numerous other enterprises for the provision of secondary or elementary education in agriculture, several of which are in active operation.

The well-known work of Hampton and Tuskegee institutes needs only to be mentioned as typical of the institutions giving agricultural instruction for a special portion of our population, and receiving their main support from private funds. The Baron de Hirsch Agricultural School at Woodbine, N. J., with maintenance expenses of about $30,000 per annum, is financed mainly by the Baron de Hirsch fund for the amelioration of the condition of Jewish immigrants, but has also received some assistance from the Jewish Colonization Association of Paris. The National Farm School at Doylestown, Pa., is a similar enterprise maintained largely by private funds. It is also of interest to note the organization in this country of the Jewish Agricultural Experiment Station, which has for its object the establishment and maintenance of an experiment station in Palestine. The collection of over $20,000 for initial equipment and the pledging of at least $10,000 per annum for current expenses is announced.

A number of gifts have been made which are restricted to a particular line of agricultural work. For example, the University of Minnesota and Harvard University have each received gifts of 2,200 acres of forest land for instruction and experimental work, and the Yale Forest School has been the recipient of large sums from the Pinchot and Jessup families and the National Lumber Association. The first chair of agricultural journalism in this country, that at the Iowa State College of Agriculture and Mechanic Arts, has owed its beginnings and a part of its subsequent maintenance to gifts of Mr. John Clay, of Chicago. A somewhat similar bequest is that of Dr. Charles A. Ring to Cornell University, the income of which is to be used in the advancement of horticultural science.

Scholarships of various kinds have been endowed at most of the agricultural colleges. One of the largest donations has been that of the late Dr. C. H. Roberts, of Ulster County, N. Y., who gave $30,000 in 1906 for five scholarships in the College of Agriculture at Cornell
University. A bequest of the late Major Henry E. Alvord to the Massachusetts Agricultural College for a dairy scholarship was made public in 1905. There have also been many bequests for the aid of worthy students in these institutions.

Since 1906, $5,000 per annum has been distributed among the state agricultural colleges in 20 scholarships, which are competed for at the International Live Stock Exposition in accordance with an offer of Mr. J. Ogden Armour. Rosenbaum Brothers of Chicago have also offered $1,000 per annum in prizes to the colleges in connection with the exposition, and other donations have been made from time to time.

A unique form of financial assistance are the industrial research fellowships at the College of Agriculture at Cornell University. Several of these have been offered for short periods by firms of manufacturers of agricultural implements and supplies, small sums being provided for the salaries and expenses of investigators along lines of work of mutual interest. The five fellowships thus far announced have dealt respectively with the value of commercial lime-sulphur mixtures as fungicides, the diseases of nursery stock, the effect of cement dust on the setting of fruit, the diseases of New York apple trees, and the nature and control of fungus diseases and insect pests of orchards in a given locality. The last two of these are supported by local fruit growers' associations.

Along extension lines, important assistance to agriculture is being rendered by the various railway systems, often in the form of direct contributions to the agricultural colleges and experiment stations for cooperative work, notably dry farming and other demonstration farms, the gifts of land for these purposes, the providing free of cost of the rolling stock for the better-farming trains so numerous in recent years, and frequently in the offering of scholarships to boys living along the railway lines. The farmers' cooperative demonstration work which this Department has been conducting in the South has received for several years the cooperation of the General Education Board of New York City, and considerable sums have also been donated by boards of trade and other local organizations.

Two bequests for permanent local demonstration work have recently become available in Massachusetts. One of these is the Faunce bequest, at Sandwich, of a farm of about two hundred and fifty acres and about $20,000 by a local physician, for use in benefiting the people of the county agriculturally. This bequest is being utilized in active cooperation with the Massachusetts Agricultural College, as a part of its extension activities. The second was one of $100,000 to the town of Hardwick, by the late Mr. Calvin Paige, a former resident. The income of this bequest is to be utilized to further the
agricultural interests of the community through the demonstration of improved methods.

If wisely planned and administered, it would seem that such bequests could be made very helpful, and the idea might well be considered as an opportunity for benefiting the people of a local community, not unlike those afforded by the village library or the town academy, which have been favorite recipients of bequests in the past.

No comprehensive review of agricultural endowment in foreign countries is attempted, but by way of illustration reference may be made to the princely gifts of Sir William Macdonald in Canada, including Macdonald College, and to the well-known instances of the Lawes Agricultural Trust and what it has accomplished at Rothamsted, the liberal aid to agricultural work at Cambridge University by the Drapers’ Company of London, and the bequest of the late Mr. John Innes, whereby $50,000 a year is available for the promotion of horticultural instruction, experiments, and research at the John Innes Horticultural Institution. A sum of nearly three hundred thousand dollars was recently bequeathed by the late Mr. S. B. Thomas for the establishment of an agricultural college in Sierra Leone, Africa. The establishment of the Imperial Agricultural College of India, located at Pusa, is attributed to its initial endowment of $150,000 by an American, Mr. Henry Phipps, of Pittsburgh. What is probably the largest bequest to agriculture yet recorded was recently announced on the death of Dr. S. N. Kolaceoskij, who has left property valued at over twenty million dollars for the establishment of an agricultural academy in southern Russia.

This cursory and incomplete review illustrates the scope and the diversity of private aid to agricultural instruction and experimentation. It has come often from unexpected sources, and it shows the gradual spread of an idea.

All these various forms of gift have been helpful in their way in working out the plan of agricultural instruction, providing for experiments in different forms in periods of doubt, developing special features, aiding needy students, and pointing out means for the improvement of agricultural conditions locally. They call attention to an opportunity for affording aid in both a small and a large way, which will redound to the benefit of the public in a quite direct manner and will give a large measure of return.

The fear that, in the case of established institutions, such gifts will result in a mere substitution of private funds for public appropriations does not appear to be well founded, for such gifts can be made to stimulate public support and to supplement it in a variety
of useful ways. The experience of the past offers many illustrations of this, and the present growth of agricultural instruction with its attendant needs multiplies the opportunity for helpful donations.

In the field of experimentation, which furnishes the backbone of instruction and extension efforts, as well as the improvement of farming efficiency, it may be pointed out that the world still lacks a large and permanently endowed institution for research in agriculture, analogous to the Rockefeller Institute in the field of medical research, for example. There is much which can not be done, or done in the way it should be, for the lack of suitable funds.

On a less pretentious scale the aiding of definite lines of inquiry, especially those to which public funds may not be immediately available, would furnish practical means of promoting inquiry in a field or special group of problems in which interest lay, and the endowment of an institution so that it could pursue such inquiries through a considerable period would be the best means of furthering such an end. The present status of agricultural research offers great opportunity for such special fundamental studies before the more simple forms of experiment can hope to make definite progress, as, for example, the functions of animal nutrition, or the physiological conditions and relationships of plant growth, or a further refinement of methods of experimentation; and in another direction the provision for certain classes of technical publications would solve a present perplexity and a great hindrance to progress.

With the recent revival of interest among nonagricultural people in agriculture and country life, and the increasing realization of the fundamental importance of agricultural development to the prosperity of the nation, greater attention to the possibilities afforded by the use of private funds may confidently be expected in the future. The situation may be summarized in the words of Sir George Clarke, in a recent address at the opening of the Poona Agricultural College, in which he says: “If the nature and vast importance of agricultural work were more widely known I am certain that our many wealthy and generous philanthropists would come forward to help. There can be no better proof of patriotism and no better way of promoting prosperity than the increase and development of the production of the land which lies within our power if adequate means were available.”
RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

[The sampling of fertilizers, soils, foods, water, feeding stuffs, and miscellaneous materials], L. Fourron (Estac. Agr. Cent. [Mexico], Cires. 27, pp. 41; 28, pp. 5; 29, pp. 6; 30, pp. 5; 31, pp. 7; 32, pp. 8).—A description of the methods of sampling utilized at the Estacion Agricola Central of Mexico.

The interpretation of color values obtained by Lovibond's tintometer, A. W. Knapp (Jour. Soc. Chem. Indus., 29 (1910), No. 23, pp. 1343, 1344).—The author points out that where two or three standard glasses are utilized for determining the color of fluids, solids, etc., no allowance is made for the stoppage of white light. He holds that this should be taken into consideration when recording results.

Methods for the rapid examination of water, A. Dané (Chem. Ztg., 34 (1910), No. 119, pp. 1057, 1058).—This is a discussion and description of rapid methods for detecting and determining nitrates, chlorides, alkalis, magnesium, sulphates, calcium, total carbon dioxide, organic matter, and Bacillus coli. Some of these methods are modifications of the standard methods in present use for water analysis.

The determination of free carbon dioxide in water, J. Tillmans and O. Heublein (Ztschr. Untersuch. Nahr. u. Genussmull., 20 (1910), No. 10, pp. 617-631, fgs. 2).—It appears from this work that the free carbon dioxide in water can be accurately estimated with limewater and other alkalis, using phenolphthalein as an indicator, providing certain precautionary measures are taken to prevent the loss of the carbon dioxide. Sulphates, chlorides, nitrates, and bicarbonates of the alkalis and alkali earth metals react neutrally toward this indicator, while rosolic acid is neutral to sulphates, chlorides, and nitrates of the alkalis and alkali earth metals, but reacts strongly alkaline with their carbonates and bicarbonates. According to this, Pettenkofer's qualitative test, which utilizes rosolic acid for detecting free carbon dioxide can not be used with certainty for small amounts of free carbon dioxide nor for large amounts when much bicarbonate is present. The quantitative determination of free carbon dioxide in water by titration with alkali or borax solution, using rosolic acid as indicator, yields inaccurate results.

Dissolved oxygen as an index of pollution, G. A. Soper and P. B. Parsons (Abs. in Science, n. ser., 33 (1911), No. 844, p. 344).—The determination of the dissolved oxygen has been found to be a good index for determining the pollution of water by sewage. The authors state that they have perfected a field method for this purpose.

The use of calcium carbide for determining moisture, I. Masson (Chem. News, 103 (1911), No. 2670, pp. 37, 38).—The author points out the advantages of using calcium carbide for determining water (E. S. R., 22, p. 513) in various agricultural products as, for instance, wood, cotton, tobacco, flour, wood pulp, paper, etc.
A method for the exact determination of ash in vegetable and animal matter, E. Fleurent and L. Lévi (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 11, pp. 715-718).—The authors found after making a comparative study between the Schloesing and the ash calcination methods with wheat, barley, dried peas, white haricots, egg yolk, horse meat, etc., that these methods furnish very variable results and do not compare well. This is due to three factors, (1) a portion of the phosphorus is acted upon by the carbon and volatilized, (2) another goes off as a volatile compound with the fatty matters, and (3) the acid phosphates of the ash are acted upon by the silica.

They, therefore, propose a method which involves (1) the removal of the fat in substances rich in fat, (2) the carbonizing in a platinum crucible at a very low temperature, (3) pulverizing the mass contained in the crucible or mixing it with milk of lime (0.04 to 0.5 gm. of calcium oxid for 10 gm. of initial substance rich in phosphorus), and (4) evaporation to dryness according to Schloesing's method. According to the authors, the method is easy and does not involve any loss.

In regard to the physiology of catalase and reductase, W. Palladin (Dnestr. XII. S° izda Russ. Est-Isp. i Vruch. [Moscow], 1910, p. 17; abs. in Zentbl. Biochem. u. Biophys., 10 (1910), No. 15-16, p. 746).—By autolyzing zymin and wheat germ upon water a decrease in the catalytic activity takes place. In the presence of NaHPO₄, the catalytic power increases markedly, while with KIIPO₄, it weakens, and KIIPO₄, completely destroys it. The author considers catalase and reductase anaerobic enzymes, but draws attention to the fact that the true enzyme nature of these bodies has not been established.

Analysis of foods, R. Guillain (Analyse des Alimentaires. Paris, 1911, pp. 480, figs. 87).—The work contains methods for the analysis of sugars, starch, flour and pastry, beverages, fats, meats, conserves, coffee, tea, and chocolate, spices, and waters, antiseptics, sweeteners, and laws in regard to food adulteration inspection.

Biological methods for detecting horseflesh in pork products, Blanc (Ann. Falsif., 3 (1910), No. 26, p. 516).—The author describes some of the difficulties encountered with the usual biological methods and the manner of procedure.

The biological method for detecting horseflesh in pork products, G. Blanc (Ann. Falsif., 4 (1911), No. 28, pp. 49-52).—This method, referred to in the article noted above, is based on the fact that when a rabbit is injected intravenously with horse serum a precipitating reagent is produced. This reagent when brought into contact in vitro with maceration extracts of horseflesh, or products containing horseflesh, produces a precipitate. It is specific for all products coming from horseflesh.

The methods of preparing the precipitating reagent and the technique for making the test are given in detail.

Composition of the ash of pickles, E. H. S. Bailey (Abs. in Science, u. ser., 33 (1911), No. 844, p. 345).—The author has made numerous analyses of the ash of normal pickles for the purpose of judging pickle conserves in regard to the addition of alum for hardening.

The determination of starch sirup in plum marmalades, A. Beythien (Ztschr. Untersuch. Nahr. u. Genussmtrl., 21 (1911), No. 5, pp. 271-280).—The author points out that it is incorrect when determining the starch sirup content of plum jams and plum marmalades to deduct 21.5 from the specific rotation of the inverted extract and then to utilize the table set up by Juckenack.a Fur-

thermore, in examining plum jams which contain no cane sugar it is essential to apply the formula \( x = \frac{100 \times 134.1}{D} \), in which \( x \) is the percentage of anhydrous starch sirup in the inverted extract and \( D \) the specific rotation of the extract. The author, however, recommends the retention of the Juckennack procedure for plum marmalades.

Biological study of honey, E. Moreau (Ann. Falsif., 4 (1911), No. 28, pp. 65, 66). — The author determined the catalytic activity, the amylolytic power, and the inverting power of 20 honeys of various kinds. The results of the invertase test are to be reported in detail later. All the honeys contained invertase.

The origin of formic acid in honey, R. Reidenbach (Leipzig. Bienen Ztg., 26 (1911), Nos. 2, pp. 21-23; 3, pp. 35-38; 4, pp. 51-55). — The presence of formic acid in honey is due to the oxidation of the sugar contained in the honey itself. It was also found to be present in the brood combs, but chiefly in combination with ammonia.

Corrosion of metallic food containers, E. Gudeman (Amcr. Food Jour., 5 (1910), No. 11, pp. 35, 36). — This is a general discussion of the subject, in addition to which the author relates his experiments in regard to obtaining a commercially feasible nonporous can with gold or antimony amalgam and enamel. The possibility of utilizing lead glass for making enameled cans is also discussed.

Detecting adulteration in feeds with the so-called anaphylaxis reaction, K. Schern (Deut. Landw. Presse, 37 (1910), No. 87, p. 945). — The author shows the possibilities of this reaction for detecting castor oil seeds (Ricinus), etc., in feeds.

In regard to Jolles' method for the quantitative estimation of saccharose among other sugars, Bruckner and Welwart (Österr. Chem. Ztg., 14 (1911), No. 3, pp. 29, 30). — The authors conclude that Jolles's method (E. S. R., 24, p. 764), when compared with other methods, can not be regarded as quantitative.

In regard to my method for determining saccharose quantitatively among other sugars, A. Jolles (Österr. Chem. Ztg., 14 (1911), No. 3, pp. 30-32). — A reply to the above, accompanied by results of cooperative work with several chemists for the purpose of showing the value of the method as a quantitative test.

Hygromipisimetry; a method for examining milk, R. Binaghi (Rev. Gén. Lait, 8 (1910), No. 16, pp. 361-371, pg. 1). — The author describes a physical method, which he terms "hygromipisimetry," for detecting adulterated milk. Some results for sheep's, goat's, and cow's milk are given.

The chemical and biological differentiation of the three proteins in cow's and woman's milk, J. Bauer and S. Engel (Biochem. Ztschr., 31 (1911), No. 1-2, pp. 46-64). — It was determined in this work that the 3 milk proteins (casein, albumin, and globulin) of cow's and woman's milk could be biologically differentiated, and that globulin is more closely related to casein than to albumin. On the other hand, albumin seemed more closely related to globulin than to casein. It was also noted that despite the biological relations of casein with the other milk proteins, the biological methods can not serve as an absolute control.
of the chemical methods for the precipitation of casein. Colostrum and blood-serum proteins behave in the same manner as those of milk and whey. The albumin and globulin of serum, milk, and colostrum, according to the authors, are probably identical.

In regard to the refractometry of calcium chlorid milk serum, G. Fendler (Ztschr. Untersuch. Nahr. u. Genussmittel., 20 (1910), No. 10, pp. 640, 641).—The author points out that the literature in regard to Zeiss's immersion refractometer does not draw attention to the fact that a correction must be applied to the refractive indexes as read off with the instrument. He, therefore, corrects some of his findings in the work with the calcium chlorid milk serum which has already been reported (E. S. R., 24, p. 612).

The value of the various chemical and physical methods for the detection of adulteration in milk and butter, C. Granvigne and G. Cassez (Ann. Falsif., 4 (1911), No. 28, pp. 77-85).—This is a discussion and study in regard to the value of different methods for detecting adulterations of milk, such as watering and the removal of cream, and the determination of fat-free dry substance, lactose, and the composition of butter.

Tests and observations in regard to the separation of water from butter, O. Hoffmeister (Molk. Ztg. [Hildesheim], 25 (1911), No. 16, pp. 271, 272).—The author sought to determine the cause for the separation of water from butter samples, but found no definite relationship existing between the separation of water and the consistency and water content of the butter. In attempting to determine the degree of water separation, he found that the amount of water was different in the various areas of the same sample, and that the samples of butter containing the highest amounts of water had the superficial appearance of being the driest.

In regard to the causes for the separation of water the author believes that these may be looked for in the various methods utilized for the manufacture of butter, and possibly in the variation in chemical composition and the mechanical structure of the fat. The analytical results for moisture obtained with Funke's apparatus and the Hesse-Röse-Gottlieb method showed that the former gave the higher results.

A new method for determining volatile fatty acids, E. Welde (Biochem. Ztschr., 28 (1910), No. 5-6, pp. 505-522; abs. in Zentrbl. Biochem. u. Biophys., 11 (1910), No. 1, p. 3).—The author modified the old method for volatile fatty acids in so far that the acids are distilled off in a vacuum with steam.

The use of glycerin in saponifying fats in the titer test, R. H. Kerr (Jour. Indus. and Engin. Chem., 3 (1911), No. 2, pp. 114, 115).—The method, which is a rapid one, is as follows:

"Fifty cc. of high-grade chemically pure glycerin (97 per cent glycerin) and 20 cc. concentrated caustic potash solution (100 gm. KOH dissolved in 100 cc. distilled water) are placed in a liter flask and warmed gently on an asbestos board over a low flame. When hot, 50 gm. of the molten fat are poured in and the flask rotated gently. Saponification begins at once and is soon complete, although there is usually some foaming before the mixture becomes clear. Complete saponification is shown by the mixture becoming perfectly clear and homogeneous. When saponification is complete the flame is removed and 500 cc. of hot water added, cautiously at first, to avoid excessive foaming. The flame is then replaced and sufficient dilute (1:3) sulphuric acid added to decompose the soap. A few minutes' boiling gives a clear layer of fatty acids. The acids are then washed and dried in the usual way. The process is quite rapid, clear acids being obtained in 20 to 25 minutes. The results show perfect agreement with standard methods."
Rapid saponification of fats for titer determination, C. V. Zoul (Jour. Indus. and Engin. Chem., 2 (1910), No. 11, pp. 579, 580).—Practically the same method as described above.

The absorption spectra of oils, R. Marchall (Ann. Falsif., 3 (1910), No. 24, pp. 423-425).—Some observations in regard to the absorption spectra of olive, peanut, sesame, cottonseed, linseed, and castor oils, with particular reference to the absorption spectra due to the presence of chlorophyll in these oils.

On the interpolation method of oil analysis, J. J. Kessler and G. K. Mathiason (Jour. Indus. and Engin. Chem., 3 (1911), No. 2, pp. 66-72, figs. 10).—This work was done with castor, cottonseed, and linseed oils and a resin and mineral oil. According to the authors, "certain tests commonly used in oil analysis (the viscosity, flash test, fire test, and Mauntené test) have been shown to follow a law of mixtures which is not an additive one, and hence if interpolations are made from the data obtained from such tests the results will be in error to a very considerable amount in some cases.

"These results call attention to the possibility of many other physical tests being nonadditive. They also suggest the possibility that certain chemical tests, in which a complete chemical reaction does not occur, may not be additive. The saponification number is shown to be an additive relationship even for small percentages of one oil in presence of another. The Mauntené test as carried out at the present time is incapable of yielding results which can be used in making a quantitative analysis by the interpolation method."

The dimethyl sulphate test of creosote oils and creosote dips; a substitute for the sulphonation test, R. M. Chapin (U. S. Dept. Agr., Bur. Anim. Indus. Circ. 167, pp. 7).—Although the sulphonation test for examining coal-tar creosote sheep dips in theory is simple and rational, its use by inexperienced persons is often unsatisfactory and is always disagreeable and tedious. In view of these facts, the author has adopted the Valenta test for the examination of such preparations. This test is based on the assumption that dimethyl sulphate is miscible in all proportions with the closed-chain hydrocarbons, while the open-chain hydrocarbons are not soluble in it at all. Some comparative results between the Valenta test and the sulphonation test are given.

Lime-sulphur spray, J. E. Harris (Michigan Sta. Tech. Bul. 6, pp. 3-9).—Recognizing the need of improvements in the way of accuracy and rapidity for the analytical methods usually employed in the analysis of lime-sulphur spray, the author, as a preliminary to work reported elsewhere, investigated the existing methods for total sulphur, monosulphid sulphur, thiosulphate sulphur, sulphite and sulphate sulphur, and calcium oxide. The work is summarized as follows:

"The total sulphur is determined by oxidizing the sulphur present to the sulphate form, using sodium peroxid as the oxidizing agent and precipitating and weighing as barium sulphate.

"The monosulphid sulphur is determined by titrating a 25 cc. sample of the diluted solution with decinormal iodin until the yellow color disappears. The number of grams per 100 cc. of the original solution is given by the computation 

\[
\text{Cc. iodin} \times 0.0016 \times 1000 
\]

25

"The thiosulphate sulphur is determined by continuing to add iodin solution after the monosulphid end point has been reached until we have one drop in

\[a\] Chem. Ztg., 30 (1906), No. 25, pp. 266, 267.
excess. This additional amount of iodin determines the amount of thiosulphate sulphur. For a 25 cc. sample the grams per 100 cc. of original solution is given by the computation \[
\text{Ce, iodin} \times 0.0064 \times \frac{1000}{25}.
\]

"Sulphate and sulphite sulphur are determined together by precipitation in the cold as barium sulphate after filtering off the sulphur from the solution used for the monosulphid and thiosulphate sulphur determinations.

"Total sulphid sulphur may be determined by dissolving the sulphur precipitate, filtered off for the sulphate sulphur determination, in concentrated potassium hydroxid, oxidizing and precipitating as barium sulphate.

"The calcium oxid may be determined by oxidizing the sulphur to the sulphate form and precipitating the calcium as the oxalate. It may also be determined by computation from the amount of iodin used in the monosulphid and thiosulphate sulphur determinations and from the amount of sulphate and sulphite sulphur present. The following computation gives the number of grams per 100 cc.: (Ce, iodin used for monosulphid sulphur) \[\times \frac{0.0028 \times 1000}{25} + \text{(sulphate and sulphite sulphur)} \times 1.75."

In regard to the advantages of these methods over old methods, it is noted that the use of sodium peroxyd as an oxidizing agent is more convenient than either hydrogen peroxyd or bromin water. Furthermore, substituting iodin titration for ammoniacal zinc chlorid solution does away with the filtering off of test portions for determining the end point by an external indicator. The dissolving of the zinc polysulphid sulphur or sulphur precipitate and the treatment of the solution with acid as a preliminary to making the thiosulphate sulphur determination are eliminated, and a "method of determining the calcium oxid present by computation from the decinormal iodin used for the thiosulphate and monosulphid sulphur determinations and from the sulphate and sulphite present" is introduced.

About a sensitive glue reaction, E. Schmidt (Chem. Ztg., 34 \(1910\), No. 94, p. 839; abs. in Zentral. Biochem. u. Biophys., 10 \(1910\), No. 17-18, p. 779).—If to a glue solution there is added, in the cold, an aqueous solution of ammonium molybdate (3 gm. to 250 cc. of water) and a few drops of dilute nitric acid, a white precipitate is produced which settles very quickly and after a short time assumes a blue-green color. The supernatant liquid also assumes this color. The precipitate dissolves on heating and only a slight turbidity remains.

Report of the activities of the agricultural experiment station at Hildesheim, Aumann (Rev. Landw. Vers. Stat. Hildesheim, \(1910\), pp. 15).—This is a report on the activities of the station from November 1, 1909, to October 31, 1910, and deals with results of analyses of artificial fertilizers (8,011 samples, of which 3,862 were Thomas slag powder); commercial feeding stuffs (8,017 samples); soils (179 samples); various commodities of the sugar industry and other technical substances and foodstuffs (2,445 samples, of which 1,184 samples were waters); and 220 samples of seeds.

Drying machinery and practice, T. G. Marlow (New York and London, \(1910\), pp. XX+326, pls. 17, figs. 174).—This is a handbook on the theory and practice of desiccating and drying, and contains a classified description of the installations, machinery, and other apparatus. The topics treated in the work which are of interest to agrotechny are the desiccation of albumin, ashes, asphalt, barley, beet and cane sugar, blood, bone meal, bran, brewery grains, cement, cocoa, distillery draff, excretions, feathers, fiber, farina, flax, flour, fruits, grain, hops, oats, leather, marl, manure, meat, molasses, phosphates, rice, rubber, spirits, superphosphates, and wood.
The drying of beets, Fabre (Suer. Indig. et Colon., 76 (1910), No. 10, pp. 224-227; abs. in Chem. Ztg., 34 (1910), No. 120, Reporter, p. 496).—The author advises pressing out the beets twice and then drying the mass with exhaust steam. By mixing the residue with finely cut straw a stable, easily transportable foodstuff containing 20 to 25 per cent of sugar can be obtained.

Molasses feeds, K. Vallier (Rev. Gén. Chim., 13 (1910), No. 23, pp. 367-370; 14 (1911), No. 1, pp. 9-14, figs. 5).—This is a general discussion on molasses feeds and the methods of manufacture. A complete description of the machinery required is given.

In regard to the preparation of adenin in molasses waste, K. Andrlík (Ztschr. Zuckerindus. Böhm., 34 (1910), No. 10, pp. 567-569; abs. in Chem. Zentbl., 1910, II, No. 9, p. 650).—The author found that by boiling molasses waste with copper sulphate and alkali about 0.05 per cent of adenin separated out. Part of it could be obtained in crystalline form by decomposing the copper precipitate with hydrogen sulphid in a concentrated solution. A further 0.03 per cent could be obtained from the mother liquor by precipitation with picric acid.

Yearbook of sugar manufacture, J. Bock (Jahresber. Zuckerfabrik. [Stam-mer], 49 (1909), pp. XII+361, figs. 25).—This is a retrospect of practically all the important work done in the sugar-producing industry for the year 1909, including agriculture, the manufacture of sugar, the chemistry of sugar, patents, statistics, and sugar legislation.

The raw materials and methods of the soft-drink industry, H. Goettler (Pure Products, 6 (1910), Nos. 2, pp. 64-71; 3, pp. 120-127; 4, pp. 178-184; 5, pp. 235-241; 6, pp. 329-323; 7, pp. 373-378; 9, pp. 591-596; 10, pp. 567-576; 11, pp. 635-639; 7 (1911), No. 1, pp. 4-10).—This is a description of the methods used for the production of various nonalcoholic drinks.

On apple aroma, E. Walter (Pure Products, 6 (1910), No. 12, pp. 696-700).—The rational manufacture of apple extract from the fresh or dried apple peels is discussed.

Alcohol from the carob bean, H. H. Morgan (Journ. Indus. and Engin. Chem., 3 (1911), No. 2, p. 139).—The tree upon which this bean grows is a leguminous evergreen and a habitat of Spain, Italy, and the Levant. The bean, which has hitherto been used as a food for animals, is from 6 to 8 in. long and about 1 in. wide.

"Experiments have lately been made in Spain to obtain alcohol from this bean. After trituriating the fruit it was immediately placed in hot water to steep and the sugar or glucose extracted by means of a current of water. The liquid resulting from the process was then allowed to ferment, the glucose thus being transformed to alcohol, which was later distilled. It was found that 2.3 qt. of pure alcohol could be obtained from 22 lbs. of the beans."

A factory has been erected at Faro, in Portugal, to manufacture alcohol from these beans.

[A new plant wax], Olsson-Seffer (Bul. Imp. Inst. [So. Kensington], 7 (1909), No. 4, pp. 410, 411; abs. in Oil, Paint and Drug Reporter, 78 (1910), No. 12, p. 2811; Chem. Ztg., 34 (1910), No. 138, Reporter, p. 567).—A new wax is described, which is obtained from the fruit of Myrrica Jalapensis. It is used by Indians and sold in Mexico for candy manufacturing purposes. The chemical and physical constants are reported.

[In regard to candelilla wax], Olsson-Seffer (Bul. Imp. Inst. [So. Ken-
sington], 7 (1909), No. 4, pp. 410, 411; abs. in Oil, Paint and Drug Reporter, 78 (1910), No. 12, p. 2811; Chem. Ztg., 34 (1910), No. 138, Reporter, p. 567).—A discussion in regard to the uses, and the physical and chemical constants of can-
delilla wax (E. S. R., 23, p. 615; 24, p. 516).
Candelilla wax (Jour. Indus. and Engin. Chem., 3 (1911), No. 2, p. 115).—A polemical article in regard to the chemistry of candelilla wax (see above).

The chemistry of and the progress in tanning technology, B. Kohnein (Osterr. Chem. Ztg., 14 (1911), Nos. 5, pp. 54-59; 6, pp. 70-73).—This is a detailed description of the progress made in the tanning and tawing processes during the last few years.

METEOROLOGY—WATER.

The work at Mount Weather included aerial research and investigations on atmospheric electricity, solar radiation, and vapor in the atmosphere. The upper air observations at Mount Weather were found to be an aid in increasing the accuracy and range of forecasts. Forecasts of certain well defined weather types for 10 days in advance were issued from time to time during the year.

Cooperation between the Weather Bureau and the Forest Service in a study of forest effects on climate and stream flow in the Rio Grande National Forest in southwestern Colorado is referred to. “Two watersheds of similar topography and of limited drainage areas have been selected, and the necessary weirs and instruments for the measurement of stream flow will be located at an approximate altitude of 9,500 ft. above mean sea level, the drainage area extending upward to an elevation of about 10,500 ft.

“It is proposed to measure the flow of the two streams for a sufficient period, probably 8 or 10 years, to demonstrate their behavior with equal forest cover. One of the watersheds will then be denuded and stream-flow measurements continued on both for another period of 8 or 10 years, by which time it is probable that the effects of the denudation, whatever they may be, can be stated in positive terms. In order that all the climatic factors that affect or modify stream flow may be considered, a complete equipment of meteorological instruments will be provided and observations will be taken several times daily. Automatic instruments will afford continuous and permanent records of pressure, temperature, wind direction and velocity, sunshine, precipitation, and evaporation.”

Experiments with various methods of measuring snowfall indicated that “snow bins, or cubical boxes, 5 ft. on a side, standing on a frame so that the top is 10 ft. above the ground . . . fitted with a system of louver on the inside to prevent the wind from blowing out the snow and to insure a level deposit within, catch very nearly the actual amount of fall.”

Observations on evaporation from Salton Sea indicate that the evaporation from the surface of the sea is about 70 in. a year. “It has been found by special experiments that the ‘Salton Sea’ ceases to exercise any influence upon evaporation during the summer at a distance of about 1,000 ft. from the shore.
This would indicate that there is no effect of the sea by way of changing the climate of the country about its neighborhood."

In cooperation with the Reclamation Service the observations on evaporation were extended to about 25 stations in the United States.

Monthly Weather Review (Mo. Weather Rev., 39 (1911), Nos. 1, pp. 1-156, figs. 3, charts 10; 2, pp. 157-316, figs. 10, charts 10; 3, pp. 317-486, figs. 8, charts 10).—In addition to the usual climatological summaries, weather forecasts and warnings for January, February, and March, 1911, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology and seismology, a condensed climatological summary, and climatological tables and charts, these numbers contain the following special papers:

No. 1.—The Pelahatchie Meteor, Which Passed Over Central Mississippi in the Forenoon of October 17, 1910 (illus.), by F. Montgomery; Orchard Heating in Indiana, by W. M. Walton, jr. (see p. 416); Deforestation and Rainfall, by G. V. Sager; The Cold Wave and the Citrus Industry, by B. Bunnemeyer; Colorado River Siphon Tunnel, and Completion of the Roosevelt Dam, Salt River Valley, Ariz., by L. N. Jesunofsky; The Minidoka Irrigation Project, by F. S. Weymouth; and The Drought of 1910 in the Principal Spring-wheat Growing States (illus.), by P. C. Day (see p. 420).

No. 2.—Correction of paper on Are the Springs Colder Now? by G. Reeder, in December, 1910, issue (illus.); Brazos River Overflows and Levee Protection, by W. W. Dibrell; Break in the Lower Colorado, by L. N. Jesunofsky; Notes on the Rivers of the Sacramento and San Joaquin Watersheds during February, 1911, by N. R. Taylor; Note upon the Weather at Redlands, Cal., by W. S. Devol; Work of the Weather Bureau in Protecting Fruit, Especially Frost Protection, by A. G. McAdie; Straw as Protection Against Frost (illus.), by A. G. McAdie (see p. 420); Irrigation in Idaho, by S. H. Hays; and The Normal Temperature of Porto Rico, West Indies (illus.), by O. L. Fassig (see p. 419).

No. 3.—The Average Stream Flow of the Savannah River, by E. D. Emigh; A Fall of Darkness, at Louisville, Ky., and Surrounding Districts (illus.), by F. J. Walz; [Change of Climate in Michigan and Kansas], by J. W. Smith; Investigation of the Water Resources of Minnesota, by R. Follansbee; Origin and Progress of Land Drainage in Bolivar County, Miss., by W. W. Boone; The Roosevelt Dam and the Salt River Project, in Arizona (illus.), by L. N. Jesunofsky; Notes on the Rivers of the Sacramento and San Joaquin Watersheds during March, 1911, by N. R. Taylor; Forecasting the Supply of Water for the Summer from the Depth of Snow (illus.), by A. G. McAdie (see p. 421); Indian Summer, by J. Morrow; and The Lowest Barometric Minima at Sea Level, by W. Krebs, trans. by C. Abbe, jr.

Meteorological observations (Maine Sta. Bul. 186, pp. 393-395).—Observations at Orono, Me., on temperature, precipitation, cloudiness, and wind during 1910 are compared with the means of similar observations for 42 years. The mean temperature for 1910 was 44.62° F., the mean for 42 years 42.37°; the precipitation for 1910, 31.68 in., for 42 years 43.41 in.; the snowfall for 1910, 52.25 in., for 42 years 90.8 in.; the number of rainy days in 1910 was 124, cloudy days 163; total movement of wind in miles, 59,812. A table is also given which shows the monthly and annual precipitation during 1910 at 18 different places in Maine.

Weather observations, M. A. Blake and A. J. Farley (New Jersey Stas. Rpt. 1909, pp. 99-112).—This is a record of observations on evaporation, rainfall, and temperature of the air and soil at the college farm at New Brunswick during 1909.
"The total precipitation for the year was 45.51 in., a departure of 1.93 in. below the normal. The rainfall was somewhat unevenly distributed and caused some injury to crops. . . . The first killing frost in the vicinity of New Brunswick occurred October 14 with a minimum of 27°. The coldest day of the year was January 19 with a minimum of −1°. The highest maximum occurred upon August 9 with a temperature of 97° . . . From May 24 to October 30 there was a loss of 3.20 in. of moisture in excess of the rainfall."

The observations on temperature showed that—

"The mean temperature of the air is lower for each month in the year than the mean temperature of the soil 3 in. below the surface. . . .

"The mean temperature of the soil 6 in. below the surface is lower for each month in the year than the mean temperature 3 in. below the surface.

"The mean temperature of the soil 9 in. below the surface is higher than the mean temperature 6 in. below the surface for the months of January, February, March, August, September, October, November, and December, but for the months of April, May, June, and July it is slightly lower.

"The mean temperature of the soil 12 in. below the surface is slightly higher than the mean temperature 9 in. below the surface for the months of January, February, October, November, and December. The month of November in the tabulations is an exception, but is not in most years. From March to October, inclusive, the temperature at 12 in. is lower than at 9 in.

"The mean temperature of the soil 18 in. below the surface is slightly higher than the mean temperature 12 in. below the surface for the months of January, February, October, November, and December. From March to October, inclusive, it is lower.

"The mean temperature of the soil 24 in. below the surface is lower than at 18 in. below the surface for each month in the year except November, December, January, and February, when it is slightly higher.

"During the months of December and January the temperature of the soil slightly increases from the 6-in. depth to the 24-in. depth; but during the months of April, May, June, and July it gradually decreases.

"An average of the monthly means for a period of years shows February to be the coldest month and July to be the warmest. There are exceptional years when January has a lower monthly mean than February; also, but much less frequently, there is an exceptional year when the monthly mean for August will be slightly higher than that of July."

The range of the minimum air temperatures for February, 1899, was from −11 to 35° and the range of the maximum air temperatures was from 4 to 53°. The range of the soil temperatures for this month and year was as follows: At 3 in. below the surface from 24 to 35°, at 6 in. 24 to 33°. at 9 in. 27 to 33°, at 12 in. 29 to 33°, at 18 in. 32 to 33°, and at 24 in. 33 to 34°. With an air minimum of −11° on the tenth and eleventh of the month the lowest soil temperature for the month 3 to 6 in. below the surface was 24°.

The maximum range of the daily air temperatures for July, 1901, was from 67 to 105°. The minimum range of the daily air temperatures was from 55 to 74°. The monthly range of the daily soil temperatures was as follows: At 3 in. below the surface, 68 to 93°, a range of 25°; at 6 in., 68 to 91°, a range of 23°; at 9 in., 70 to 89°, a range of 19°; at 12 in., 71 to 86°, a range of 15°; at 18 in., 70 to 81°, a range of 11°; and at 24 in., 70 to 77°, a range of 7°.

The normal temperature of Porto Rico, West Indies, O. L. Fassig (Mo. Weather Rev., 39 (1911), No. 2, pp. 299-302, figs. 5).—This article summarizes observations at 43 stations in the island, covering a period of over 11 years.
These observations show that "the mean annual temperature for the island of Porto Rico as a whole is 76.3°, a comfortable and healthful temperature when accompanied, as it usually is in Porto Rico, by the fresh winds of the northeast trades, and a relatively high percentage of overcast skies. The stations on the coastal plain have a somewhat higher mean temperature, about 78° along the north, west, and south coasts, and about 79° along the east coast. At inland stations the mean temperature is below 76°, varying from 76 to 72°, according to elevation above sea level and other local conditions. The lowest temperatures are found, as usual, at the higher elevations, at stations from 2,000 to 2,500 ft. above sea level on the main divide, a range of mountains crossing Porto Rico from east to west a little south of the center of the island.

"The average annual temperature of the island has varied but little from the normal during the past 12 years. In 1901, the warmest year of the period, the average was 1.3° above the normal, and in 1907, the coolest year, 0.5° below. The average temperature was above normal for the island as a whole from 1900 to 1903, inclusive, and normal or below from 1904 to 1910, inclusive. During the year 1910 the temperature continued below normal from January to November, inclusive."

January is as a rule the coldest month, with a general average of 73°; August the warmest, with an average of 79°. During the winter months the mean daily temperature varies from 75 to 76° along the immediate coast, decreasing to 74° over most of the coastal plain and ranging from 72 to 68° at inland stations, depending upon the elevation. During summer and early fall the mean temperature along the coast is 80 to 81°, rising frequently to 82 to 83° along the east coast. At inland stations the mean summer temperature varies from 74 to 76°. There is a fairly constant difference of 6 to 8° between coastal and inland stations throughout the year.

There is a comparatively large diurnal variation in temperature. "At stations on the immediate coast, like San Juan, or on the smaller islands, like Culebra and Vieques, the diurnal range is influenced by surrounding ocean temperatures and is quite small, from 10 to 11°. At all inland stations, and practically all the towns of Porto Rico are 2 or more miles from the coast, the mean daily range is from 20 to 25°, according to local topography."

Meteorology (New Zeal. Off. Yearbook 1910, pp. 403-410).—Tables summarize the results of observations on temperature, rainfall, atmospheric pressure, and wind at 16 stations throughout New Zealand during the year 1909, as well as compare the shade temperature for each month in New Zealand with that of other British states and colonies.

Straw as protection against frost, A. G. McAdie (Mo. Weather Rev., 39 (1911), No. 2, pp. 276-278, figs. 3).—The action of straw in preventing the formation of frost near the surface of the ground is explained, and the need of investigation on this subject is pointed out.

The drought of 1910 in the principal spring-wheat growing States, P. C. Dav (Mo. Weather Rev., 39 (1911), No. 1, pp. 142, 143, figs. 2).—This article describes the drought of 1910, which was particularly severe during the crop season in the great spring-wheat region of North Dakota, Minnesota, Wisconsin, Iowa, Nebraska, South Dakota, Montana, and adjoining portions of the Canadian northwest.

It is stated that "over much of this region the precipitation did not equal 50 per cent of the usual annual fall, and the deficiency during the period of spring-wheat growth was even greater in proportion." An examination, however, of charts prepared from the available rainfall data "shows that the area of greatest deficiency in precipitation does not coincide identically with the area of greatest loss to crops. In central and eastern Minnesota, where the rainfall
deficiency was greatest, a good crop of wheat was grown and other crops made fair returns, whereas in North Dakota, while the deficiency in precipitation on the whole was not nearly so great, crops were to a large extent nearly total failures. This was due in some measure to the fact that there is normally considerably more rainfall in the eastern portion of the district than in the western, so that while the deficiency was greater, the actual rainfall was still sufficient for fair crop growth.

It is thought that the prime cause of severe crop failure in some cases was the intense heat which prevailed, particularly in the northern and western portions of the district. "Experienced farmers have stated that had normal temperatures been experienced during this critical period fair crops would have been harvested despite the deficient rainfall. Over the more eastern and southern portions of the district high temperatures were less persistent and the damage to crops was not so great."

Forecasting the supply of water for the summer from the depth of snow, A. G. McAdie (Mo. Weather Rec., 39 (1911), No. 3, pp. 435-447, figs. 2).—This article briefly discusses this subject on the basis of observations at Summit, Placer Co., Cal., at an elevation of 7,017 ft., and describes a simple mechanical device for comparing total precipitation, snowfall, run-off, and rate of melting of snow with a view to predicting the rate of disappearance of the snow in the mountains and the probable water supply. The data upon which the discussion is based are given in detail.

Surface water supply of the Ohio River basin, 1909, A. H. Horton, M. R. Hall, and R. H. Bolster (U. S. Geol. Survey, Water-Supply Paper No. 263, pp. 192, pls. 6).—This is one of the series of papers on the surface water supply of the United States, and gives the results of flow measurements on the Ohio River and its tributaries, covering a drainage area of about 210,000 square miles.

Surface water supply of the Hudson Bay and Upper Mississippi River basins, 1909. R. Follansbee, A. H. Horton, and R. H. Bolster (U. S. Geol. Survey, Water-Supply Paper No. 265, pp. 231, pls. 4).—This is one of the series of papers on the surface water supply of the United States, and gives results of flow measurements of streams in the drainage areas tributary to Hudson Bay and the Upper Mississippi River.

Preliminary report on the ground waters of Estancia Valley, New Mexico, O. E. Meinzer (U. S. Geol. Survey, Water-Supply Paper No. 260, pp. 33).—This is a preliminary report upon the underground waters of this valley, which covers an area of about 2,000 square miles near the geographic center of New Mexico.

It is stated that "the underground supply is too small to irrigate more than a small part of the valley, but it is sufficient to add materially to the prosperity and comfort of the people. Even where the depth to water is great, the irrigation of a garden, lawn, and orchard will generally be feasible. In the central area, however, the presence of alkali may seriously impair the quality of the water or may prohibit its use. Taken as a whole, the water of Estancia Valley is a valuable resource that should be developed, but its development should be conducted carefully and with full cognizance of the inherent limitations."

"In spite of the high cost of fuel, if the water is lifted in the most economical way and is wisely used, pumping for irrigation can under favorable conditions be made profitable."

Geology and underground waters of southern Minnesota, C. W. Hall, O. E. Meinzer, and M. L. Fuller (U. S. Geol. Survey, Water-Supply Paper No. 256, pp. 406, pls. 18, figs. 9).—The purpose of the investigations here reported was "to determine to the fullest practicable extent the principal facts in regard to
the underground waters—their quantity, head, mineral quality, sanitary conditions, and their depths beneath the surface—as well as the best methods of drilling to them and finishing wells for their utilization and to consider all other questions relating to their recovery for human use.”

The region investigated included approximately the southern two-fifths of the State of Minnesota, covering an area of 28,365 square miles. In nearly all cases a careful examination was made of the sanitary quality of the waters. The work was done in cooperation with the University of Minnesota.

The bacteriology of water: Its present position, P. F. Frankland (Jour. Soc. Chem. Indus., 39 (1911), No. 6, pp. 319-334).—This article discusses the development of the present methods of bacteriological examination of water and explains their importance in supplementing chemical analysis.

The author concludes that “in those cases in which the source and general characters of a water supply are well known, the variations in purity from day to day or from week to week can undoubtedly be more satisfactorily watched by means of bacteriological examination. On the other hand, it is often desired by means of a single examination to ascertain the fitness or otherwise of a water for domestic use, and in such cases the omission of a chemical analysis may lead to an entirely erroneous opinion being formed. The ingredients detected by chemical analysis—organic matter, ammonia, nitrates, chlorids, etc.—on which an opinion as to hygienic quality is based, are all much more permanent and uniform features in the composition of the water than are the amount and the nature of the bacterial life which it may contain. The chemical analysis will, therefore, if skillfully interpreted, enable a much better idea of the potentiality of the water to be obtained than would be possible from a single bacteriological examination.”

SOILS—FERTILIZERS.

Agricultural chemistry and vegetable physiology, A. D. Hall (Ann. Rpts. Prog. Chem. [London], 7 (1910), pp. 208-224).—This is a brief review of progress in investigations during 1910 on soils, soil bacteriology, chemistry of the growing plant, manures and manuring, and the chemistry of animal nutrition.

It is stated that during this year no outstanding paper comparable to Russell and Hutchinson’s work, which appeared in 1909, was published, but that activity was “well maintained in all departments of the subject, and particularly in connection with vegetable physiology several valuable and suggestive investigations have been reported. No additions have been made during the year to our knowledge, of the action of protozoa in the soil, although several independent investigators have arrived at results which fit in with the theory outlined by Russell and Hutchinson, and in a general discussion on the subject which took place at the Sheffield meeting of the British Association some promising applications to practice were reported in connection with the treatment of greenhouse soils which, although rich in manure, rapidly become unsuitied for vegetation, and again in connection with the treatment of the soil of sewage farms.”

Special attention is called to Cameron’s paper (E. S. R., 23, p. 714) giving a general survey of the Bureau of Soils theory of soil productiveness and fertilizer action; the work of A. Koch on the effect of sugar and other carbohydrates on nitrogen fixation by Azotobacter; and the work of Upliani and others on the changes which take place when cyanamid is added to the soil.

Colloid studies in scientific soil investigations, E. Ramann (Kolloidchem. Beihefte, 2 (1911), No. 8-9, pp. 285-303, figs. 5).—This is a review of the
present knowledge of the subject. The author is of the opinion that colloid investigations to date have been chiefly concerned with a study of pure adsorptive processes, and that more attention should be given to the study of the more important process, from the standpoint of soil and plant nutrition, of adsorption by exchange, and to changes in the character of colloids due to increase in content of absorbed compounds and protective colloids.

Bacteriological methods for the estimation of soil acidity, J. G. Lipman (Science, n. ser., 33 (1911), No. 860, pp. 971-973).—This article notes the lack of a satisfactory method for the quantitative estimation of soil acidity and suggests the use of a method based upon bacteriological reactions. Preliminary experiments are reported which show "that the amount of acid present in cultivated soils may be determined quite accurately by comparing bouillon of varying reactions with equivalent quantities of neutral bouillon containing varying amounts of soil." The proposed method may utilize either ammonifying, nitrogen-fixing, or nitrifying organisms. It is stated that a full report on this subject is being prepared.

The Remy method gave unsatisfactory results. In the beaker method "100 gm. quantities of soil [were] thoroughly mixed with 0.5 gm. of peptone. At the end of 3 or 4 days these portions of soil, kept in covered beakers and maintained at the same moisture content by means of sterile water, were transferred to copper flasks and the ammonia was distilled off and determined."

By neither method was there shown to be any direct relation between the number of bacteria and ammonia formation, but "the methods employed were capable of measuring with a fair degree of accuracy the differences in numbers and nitrate formation." Further experiments indicated a relation between the ammonia formed and the amounts of peptone, dried blood, and cottonseed meal used in cultures.

In a study of various factors affecting ammonia and nitrate formation it was found "that the production of available nitrogen compounds is affected not only by the amount of nitrogenous material present or applied, but also by the depth of soil; that is, the absolute quantity of soil in which a given quantity of nitrogenous fertilizer is distributed."

"In materials like cottonseed meal and dried blood the rate of decomposition is affected up to a certain point by the volume of soil in which they are distributed; that is, by variation in the physical, chemical, and bacteriological factors involved. . . . The results emphasize in a practical way the importance of thorough distribution in the soil. We know that in field practice or under market-garden conditions, even when relatively small amounts of nitrogenous materials are used, the distribution may be so unsatisfactory as to bring a comparatively small amount of soil in contact with a comparatively large amount of fertilizer. Under such conditions the rate of ammonification and of nitrification is likely to be affected in an unsatisfactory manner as indicated by the present experiment."

In continuation of previous experiments (E. S. R., 22, p. 120) showing a certain periodicity in the accumulation of nitrates in soils, experiments were made to show the effect on nitrification of adding varying amounts of nitrate to the soil. The results showed "that the addition of sodium nitrate readily affected the accumulation of nitrate nitrogen in the soil. When 0.2 gm. of NaNO₃ were added the accumulation of nitrate was enhanced at the end of 2
weeks as compared with the blank soils. In the following 2 weeks the accumulation of nitrate nitrogen was depressed, showing a deficit of nearly 7 mg, as compared with the corresponding blank soils. After that there was an enhanced accumulation until at the end of 8 weeks the addition of the 0.2 gm. of NaNO₃ had resulted in a greater accumulation of nitrate nitrogen equivalent, on the average, to 12.915 gm."

The author concludes that "periodicity in the accumulation of nitrates in the soil may be due to both the temporary prominence of species especially capable of transforming large amounts of nitrate into protein nitrogen as well as to the mere rapid increase of various decay organisms and their intense utilization of nitrates for the building of their bodies."

Investigations on methods of determining the lime requirements of soils, H. R. Christensen and O. H. Larsen (Centbl. Bukt. [etc.], 2. Abt., 29 (1911), No. 12-14, pp. 357-380).—These investigations have already been noted from another source (E. S. R., 24, p. 527).

The color of soils, W. O. Robinson and W. J. McCaughey (U. S. Dept. Agr., Bur. Soils Bul. 70, pp. 29, figs. 2).—This bulletin reports the results of studies on causes of colors and their relation to productiveness in soils, with particular reference to red and yellow soils, and on physical and chemical properties of iron compounds and their solutions.

"Generally speaking, the color of a soil is dependent upon the content of organic matter and ferric oxid, the latter being more or less hydrated. The thicker the film of organic matter and ferric oxid coating the soil grains, the darker the soil... It is probable that the thickness of film surrounding the soil particles is the predominant factor determining color."

Decaying organic matter was found effective in causing a solution of iron in the soil water. The dissolved iron is transported only to a limited extent, owing to the readiness with which it is oxidized to the slightly soluble ferric oxid. It is usually reprecipitated within a short distance, frequently filling crevices from which its parent mineral has been removed.

The authors are of the opinion that sufficient difference does not exist between soil temperature of the northern and southern States to cause a change from a hydrated to a dehydrated iron oxid. Mineralogical examinations showed a larger proportion of secondary quartz grains in red than in yellow soils, the secondary grains being characterized by included iron stains and by not possessing the clear gaseous or liquid inclusions which characterize the primary quartz particles. Basic rocks, or rocks rich in ferrous minerals, yield a red soil, and acid rocks, which are relatively low in iron-bearing minerals, yield a yellow soil.

Red soils may also result from yellow soils by continued weathering agencies with little erosion, and yellow soils from red soils where erosion agencies and water transport have been active.

The movement of soil material by the wind, with a bibliography of eolian geology, E. E. Free and S. C. Stuntz (U. S. Dept. Agr., Bur. Soils Bul. 68, pp. 272, pls. 5, figs. 2).—This bulletin brings together, correlates, and summarizes the known data of eolian geology as bearing upon soil formation, translocation, and control. It includes not only a comprehensive review of the literature of the subject but also many of Mr. Free's own observations, made in many cases to clear up obscure points or apparent discrepancies in the work of other investigators. An extended bibliography is given.

The discussion emphasizes the fact that the wind plays an important part in soil genesis, "and is not the least of the great dynamic agents which we now know affect the soil... Wind action, both in removal and transfer, must be regarded as an important item in the newly emphasized dynamic explanations of the soil and its fertility."
"The soil-forming actions of the wind may be classed roughly under two headings, soil removal and soil mixing. In removal the wind is but one of several agents (of which running water is probably the chief) which, by removing weathered soil material from the land surface into the sea, progressively expose the rocks beneath to the processes of decay, enabling the maintenance of that balance upon which depends the permanence of the soil layer. Among these agents the wind is greatest only in areas of considerable aridity, and even there it is by no means the sole active factor. From our present viewpoint, the second or mixing action is of far greater and more general importance. The carrying of soil material from place to place across the land surface makes possible, as already discussed, the existence in any particular soil of minerals not present in its parent rocks, and is one cause of the well-known and remarkable constancy with which the useful minerals occur in the soils of the world. In this action the wind shows its greatest effectiveness. As a mixer of soils already formed, it yields to none. Nor is this action, like the former, confined to arid lands. . . . Even in humid regions there is much movement of soil by wind and soil mixing by such movement is a factor which must not be neglected," a fact well illustrated by one of the author's observations on the wind-blown sands of Anne Arundel County, Md.

Soil erosion, W J McGee (U. S. Dept. Agr., Bur. Soils Bul. 71, pp. 60, pls. 33, figs. 3).—This bulletin discusses the agricultural duty of water, the duty of the soil, the natural and abnormal work of water in agriculture, and remedies for soil erosion based on treatment of the soil by tillage, mulching, fertilizing, seasonal plowing, draining, and dust mulching; the treatment of cover by tree planting, grassing, nurse cropping, cover cropping, eradication of weeds; and rotation of crops; the treatment of slopes by contouring, terracing, vineyards, retain-walling, annular forestation, and grading; and the treatment of the water supply by regulating its movement.

The author summarizes the requisites for the maintaining of a natural balance between cover, soil, and slope as "(1) to retain mulch and humus, partly to hold the waters of rains and snows, partly to temper and so increase the friability and sponginess of the soil; (2) to till deeply in order that the soil body may be kept open to free circulation of the soil fluid; (3) to select crops partly for the sake of affording cover for the longest practicable portion of the year, especially on steeper slopes; (4) to rotate crops partly for the sake of alternating long and short seasons of cover and so checking any erosion started by defective cover; (5) in the dearth of vegetal mulch, to maintain a dust mulch tending to check evaporation from the surface and thus to promote circulation through the crop plants; and (6) on all steeper slopes to plow and plant on contours, thereby closing gullies and channels and retarding run-off. . . ."

"The several modes of treatment designed to remedy or prevent soil erosion are alike in principle—all operate through regulating the movement of water. The primary object is conservation of both solid and fluid parts of the soil through a balanced distribution of the water supply. The ideal distribution is attained when all the rainfall or melting snow is absorbed by the ground or its cover, leaving none to run off over the surface of field or pasture; in which case the water so absorbed is retained in the soil and subsoil until utilized largely or wholly in the making of useful crops, while any excess either remains in the deeper subsoil and rocks as ground water or through seepage feeds the permanent streams. Although this ideal distribution can commonly be brought about by proper treatment, it frequently fails on account of (a) inequality of supply, (b) catastrophic storms, (c) defective drainage,
and (d) thriftless farming. In these cases the evil may be palliated rather than prevented, and by collective rather than individual action."

Investigations on the chemical and mechanical composition of pine forest soils and analyses of ash of pine trees, J. Vityn (Zhur. Opyt. Agron. (Russ. Jour. Exp. Landsc.), 12 (1911), No. 2, pp. 171–203).—The results of the work here reported showed that the total amounts of phosphoric acid, lime, and potash soluble in hydrochloric acid were much larger for podzol soils underlain with clay strata than for soils over sand strata. All soils underlain with sand strata were similar in their phosphoric acid, lime, and potash content, and the difference in growth of pine trees may possibly be explained by the difference in marshiness of the soil, the latter factor influencing also the process of soil formation, especially with regard to the distribution of the aluminum and iron oxides.

Increasing marshiness tends to reduce the iron oxid (Fe₂O₃) content in the upper humus layer of the soil. In podzol soils the aluminum and iron oxides tend to accumulate nearer the surface than in marshy soils (peaty podzol soils). The aluminum oxid was deposited at a greater depth than the iron oxid. Podzol soils contained substantially the same quantities of iron and aluminum oxides in the hardpan (ortstein) layer, whereas marshy soils contained less aluminum oxid than iron oxid, a considerable part of the former seemingly being carried away with the drainage water.

The ash content was highest in pine trees from marsh soil forests, the heart wood containing somewhat more ash than the sap wood. This is contrary to the usual observation and may be due to the fact that the trees were relatively young (70 years old).

The use of soils east of the Great Plains region, M. Whitney (U. S. Dept. Agr., Bur. Soils Bull. 78, pp. 292, pl. 1, figs. 16).—The purpose of this bulletin is to indicate the proper use of soils in the production of the several staple farm crops, dairy products, fruits, and vegetables, based upon the work of the Bureau of Soils, which, up to January 1, 1910, covered 105,613,576 acres in the following soil provinces: Atlantic and Gulf Coastal Plains 32,576,360 acres, Piedmont Plateau 10,306,426 acres, Glacial and Loessial 24,562,696 acres, Glacial Lake and River Terrace 7,586,286 acres, Limestone Valleys and Uplands 7,666,814 acres, Appalachian Mountains and Plateau 10,158,817 acres, and the River Flood Plains 12,756,177 acres. An attempt is also made to bring out plainly the relationships and essential differences of the soils and to work out their genetic classification. A complete list of changes in names necessary to the perfecting of the classification is given.

The Cecil sandy loam, J. A. Bonsteel (U. S. Dept. Agr., Bur. Soils Circ. 27, pp. 19).—This is the fifth of a series of circulars on soils of the Eastern United States and their use, and deals with the Cecil sandy loam, of which an aggregate of 3,143,900 acres in 29 different areas located in 5 States has been surveyed by the Bureau of Soils.

The Cecil clay, J. A. Bonsteel (U. S. Dept. Agr., Bur. Soils Circ. 28, pp. 16).—This is the sixth of a series of circulars on soils of the Eastern United States and their use, and deals with the Cecil clay, of which a total of 2,490,627 acres in 32 different areas located in 7 States have been surveyed by the Bureau of Soils.

The Hagerstown loam, J. A. Bonsteel (U. S. Dept. Agr., Bur. Soils Circ. 29, pp. 18).—This is the seventh of a series of papers on soils of the Eastern United States and their use, and deals with the Hagerstown loam, of which 1,211,911 acres in 24 different areas in 5 States has been mapped by the Bureau of Soils.

The heaths of Uckermünde, H. Selheim (Die Uckermünde Heide. Inaug. Diss. Univ. Greifswald, 1910, pp. IX+116, pl. 1, figs. 10, map 1).—This is
a thesis submitted for the degree of doctor of philosophy at the University of Greifswald. The author discusses the extent, topographic features, formation, vegetation, settlement, and commercial importance of the heath lands surrounding Uckermünde, Pomerania. The character of the soil and the changes it has undergone are discussed. A bibliography is appended.

Moor culture plat experiments, 1910, II. Von Feilitzen and A. Bauman (Svenska Mosskulturfor. Tidskr., 25 (1911), No. 2, pp. 157-173).—Experiments on 65 plats in 18 different counties in Sweden were arranged for by the association. The experiments included tests of soil amendments and fertilizer and variety tests with small grains and soiling and hay crops.

The problem of “bare patches,” W. A. Hargreaves (Jour. Dept. Agr. So. Aust., 15 (1911), No. 9, pp. 836-846).—The author reports the results of chemical analyses and of pot tests of soils from different localities of South Australia to determine the cause of the infertile portions (bare patches) of these soils.

It is concluded that the sterility is due to excessive quantities of soluble salts. Chlorids and sulphates seemed to predominate. The probable action of the soluble salts in retarding plant growth is discussed.

Carbon bisulphid as soil renovator, C. J. J. van Hall (Teussmannia, 22 (1911), No. 2-3, pp. 152-162).—This is a brief review of experiments by other investigators.

Citrus experiments, A. W. Blair (Florida Stu. Rpt, 1910, pp. XXV-XXXIV, figs. 6).—This is a brief account of the plan and progress of these experiments, dealing especially with the fertilizers used, the installation of air and soil thermographs, the composition of soils used and of orange leaves and stems grown on the experimental plats, and the installation of soil tanks for supplementary studies on the fertilizer requirements of citrus fruits (E. S. R., 25, p. 117).

Heavy root feeding and the dungheap, J. Hendrick (Trans. Highland and Agr. Soc. Scot., 5. ser., 23 (1911), pp. 32-39).—It is shown in this article that about $5 per cent of the nitrogen consumed by animals in case of heavy feeding with roots is lost in the form of liquid manure, this loss being much greater than in the case of feeding with linseed cake or other concentrated nitrogenous feeding stuffs.

The production, control, and use of commercial fertilizers, T. Alexander (Österr. Chem. Ztg., 14 (1911), No. 7; pp. 82-87; abs. in Chem. Zentralbl., 1911, 1. No. 18, pp. 1374, 1375).—This is a general review of the subject with special reference to Austrian conditions.

Vegetation experiments with miscellaneous materials used as direct or indirect fertilizers, J. G. Lipman, P. E. Brown, and I. L. Owen (New Jersey Stas. Rpt. 1909, pp. 183-208, pls. 7).—Pot tests of “phospho-plaster,” a by-product of superphosphate manufacture, low-grade rock phosphate, peat, calcium carbonate containing a small amount of borates, gypsum containing boric acid, and greensand marl are reported.

The peat tested in these experiments was from a deposit in Warren Co., N. J., which is being exploited as a fertilizer and fertilizer filler and contained, sun-dry, 1.66 per cent of nitrogen, and “bone-dry,” 2.06 per cent of nitrogen. In experiments with rye the application of 1 gm. of nitrogen in the form of sun-dry humus increased the yield of dry matter from 2.15 gm. to 7.6 gm., while 2 gm. of humus nitrogen increased it to 11.4 gm., and 3 gm. to 13.5 gm. of dry matter. A similar increase occurred also in the pots where bone-dry humus was used, except that the absolute yields were not as large. Furthermore, the increasing amounts of humus increased the proportionate amount of nitrogen in the dry matter. The nitrogen of the sun-dry humus was more available than that of the bone-dry humus. Evidently the drying of the
material at higher temperatures reduced still further its resistance to the decomposition processes in the soil. At best, however, the availability of the humus nitrogen was very low. The highest recovery of the applied nitrogen was only 7.17 per cent in the case of the sun-dry humus, and only 5.17 per cent in the case of the bone-dry humus.”

The authors estimate on the basis of their results that the peat experimented with is worth not more than $1 per ton as a fertilizer, “a price at which its commercial exploitation could not be made profitable.” It may be used more profitably as a litter or fertilizer filler. “There is no objection to the use of peat as a filler in complete fertilizers or as a diluent in incomplete fertilizers, like dried blood, provided that no attempt is made to charge for the peat nitrogen the same price that is charged for dried blood nitrogen. Unfortunately this is exactly what is being done in many instances.”

The results with greensand marl were inconclusive and with the other materials not of general interest.

Experiments with different nitrogenous fertilizers for spring grains and root crops, F. Hansen (Tidsskr. Landbr. Plantecel, 17 (1910), No. 5, pp. 693–731).—The fertilizers experimented with were nitrate of soda, Norway salt peter (calcium nitrate), calcium cyanamid, sulphate of ammonia, and liquid manure. The experiments were conducted during the years 1904 to 1909 at six of the Danish experiment stations.

The average effects of the different systems of fertilization for all fields and years were as follows, the value of the nitrate of soda being placed at 100: Norway salt peter 79 and 88 for roots and spring grains respectively, ammonium sulphate 71 and 96, calcium cyanamid 42 and 74, and liquid manure 65 and 72. The average effect of calcium cyanamid on fields in which the fertilizer was plowed under was 68.

The after effects of the various fertilizers observed during the season of 1910 were not marked, but appeared especially after calcium cyanamid and ammonium sulphate. Cooperative trials with these fertilizer materials conducted by county agricultural societies gave results that agreed well, on the whole, with the averages obtained at the experiment stations.

As to methods of application, nitrate of soda gave slightly better results both for roots and small grains when one-half was plowed under and one-half used as a top-dressing, while the largest yields were obtained with the other mineral fertilizers when these were plowed under.

Cyanamid in complete fertilizers (Amer. Fert., 34 (1911), No. 12, pp. 46, 47).—Directions are given for the mixing of cyanamid with other fertilizing materials in the preparation of complete fertilizers. A table is given which shows the amounts of cyanamid which must be used to furnish different percentages of ammonia in fertilizer mixtures.

After effects of phonolite as a potash fertilizer, S. Rhodin (K. Landbr. Akad. Handl. och Tidstr., 49 (1910), No. 8, pp. 691–695).—The after effects of phonolite were studied with grass and green oats in three different series of trials. The solubility of the potash was not found to have increased during the second season, and both these experiments and recent trials conducted by the Swedish Moor Culture Society show that ground phonolite can not replace the Stassfurt salts, which are immediately available, effective, and cheaper as potash fertilizers.

Potash in China, L. Bergholz et al. (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 141, pp. 1228, 1229).—Reports from consular agents in different parts of China are given which show that there is considerable domestic trade in potash derived from wood ashes in various Chinese provinces. An apparently unverified report that potash deposits have been discovered in Shantung
Province is referred to. There is no information as to the occurrence of such deposits in other provinces.

The settlement of the potash controversy (Chem. Indus. [Berlin], 34 (1911), No. 11, pp. 305, 306).—The terms on which the disagreement between the Potash Syndicate and American purchasers was settled on May 21 are briefly stated.

Preparation of dicalcium phosphate, P. Palmaer (Teknisk Tidsskr., 40 (1910), p. 157; abs. in Chem. Ztg., 35 (1911), No. 11, Report., p. 32).—The preparation of dicalcium phosphate by treatment of crude phosphate with acid obtained by electrolysis of sodium chlorate or perchlorate with the subsequent regeneration of the electrolyte is described in this article. The phosphoric acid of the dicalcium phosphate obtained by this process was 35 per cent soluble in citrate solution.

On the after effects of phosphate, H. G. Söderbaum (Meddel. Centralanst. Försökssv. Jordbruksområdet, 1911, No. 37, pp. 22, figs. 6; K. Landlthr. Akad. Handl. och Tidsskr., 50 (1911), No. 3, pp. 218–236, figs. 6).—Comparative experiments with oats and barley fertilized with superphosphate, dicalcium or tricalcium phosphate, or bone meal, applied either with or without lime, showed that during a period of five years insoluble phosphates applied the first year produced an increase in crop yield amounting to about 70 per cent of that obtained during the same time by a corresponding amount of soluble phosphoric acid (superphosphate) which was likewise given the first year only. In cases where the conditions, especially the lime factor, were less favorable for the assimilation of the insoluble phosphoric acid, the increased yield was only 10 per cent or less. In the opinion of the author it may properly be questioned whether the after effects of insoluble phosphates are of sufficient practical importance to be considered in the calculation of the market value of bone meal and triposphates.

Use of lime on land ([Philadelphia], 1911, 7, ed., pp. 8).—This is the seventh edition of a small pamphlet “edited by the school of agriculture and experiment station of the Pennsylvania State College,” giving directions regarding the use of lime on land and a list of dealers in agricultural lime, ground limestone, and fertilizers in Pennsylvania.

Fertilizers, C. S. Cathcart (New Jersey Stas. Rpt. 1909, pp. 15–23).—This is a brief report on fertilizer inspection in New Jersey in 1900 reported in detail in Bulletins 223 and 224 of the station (E. S. R., 22, pp. 228, 625), and which involved analyses of 762 samples of complete fertilizers representing the product of 108 manufacturers, besides samples of miscellaneous fertilizing materials. Tables are given showing the wholesale cost per pound of fertilizing constituents in raw, unmixed materials, and the quality of the different brands of fertilizers examined.

Tabulated analyses of commercial fertilizers, W. Frear (Penn. Dept. Agr. Buls. 199, pp. 105; 203, pp. 75).—These bulletins give the results of analyses and valuations of fertilizers examined under state law in Pennsylvania during 1910. Of the 730 samples of complete fertilizers examined during 1910, 230 were deficient in one or more constituents.
The book treats of plant physiology with special reference to plant production. It does not pretend to treat exhaustively any topic but offers a wide range of material showing plant behavior under all conditions. As such it should be of value in agricultural, horticultural, and other classes where a knowledge of plant activity is of high importance as a part of the training for practical and rural life. The different chapters are followed by series of suggestive laboratory exercises for students by which the principles described are clearly demonstrated. References to special articles are freely given, and numerous textbooks are cited for fuller discussions of the principles involved. A feature of the work is the frequent use of illustrative material from plants that are familiar and directly useful rather than the standard illustrations drawn from rare and often unattainable material.

The plant cell, H. A. Haig (London, 1910, pp. IX+297, table 1, pls. 12, figs. 112).—The text deals with the study of structural and physiological botany from a biological standpoint. The working substance of a cell, the protoplasm, is given first place in importance, and the subsequent changes in form, function, etc., are looked upon as being due to the protoplasm under the stimulus of various physical and chemical forces.

The water supply and the osmotic pressure conditions of desert plants, H. Fitting (Ztschr. Bot., 3 (1911), No. 4, pp. 269-275).—This is an extended investigation of the means by which desert plants obtain their water, special attention being given to the water-absorbing power of certain desert species as indicated by their intensified osmotic pressure.

The results are given of tests of the osmotic pressure of plants of stony deserts, of extremely dry, rocky deserts, of desert plants when grown in damp soils, of plants growing on very saline, wet soils, of dune plants, and of some plants from the Desert of Oued Biskra.

It is claimed that neither annual nor perennial plants in the Sahara Desert replenish their loss of water from dew, as there is no dew in this region, and also that only to a limited extent can most of the perennial desert plants draw on the very deep ground water, because the soil conditions for many of the common kinds of plants are such as to make it impossible for their roots to penetrate to any great depth. Careful studies of the vegetative conditions of desert plants force the conclusion that in such dry deserts as the Sahara the water supply of perennials which have no storage tissues must come from the upper dry-soil layers. It is also stated that in very dry years the nonxerophytic annuals obtain their water supply from the uppermost dry-soil layers.

From the author's observations and investigations it seems probable that perennial desert plants have developed distinct adaptations and devices to draw from the very dry soil the necessary moisture for plant growth. Such adaptation would be the development of a very high osmotic pressure by which means the plant would be enabled to absorb water from even the dry soil. It was found that the osmotic pressure of many of the desert plants (a list of which is given, together with their osmotic pressures) was very high, and varied materially for the different species tested.

Of the 46 species investigated, 21 per cent had an osmotic power of 3 gm. of potassium nitrate, which is equivalent to a pressure of 100 atmospheres, 35 per cent had a pressure greater than 1.5 gm. (53 atmospheres), 52 per cent had a pressure higher than 1 gm., and only 11 per cent had an osmotic pressure as low as 0.3 to 0.6 gm. The lowest pressures were found in the annuals, and the highest in the shrubs. Of the 10 species with a pressure of 3 gm. or more, 6
were found to be very rich in sodium chloride. No positive relationship was found to exist between the formation of water reservoir tissues and the osmotic pressure of desert plants.

The author concludes that perennial plants of the extreme desert type develop a high degree of osmotic pressure, that many of them have the power to regulate this pressure according to the dryness of the region in which they grow, and that both of these characters enable the plants to withdraw moisture from very dry soils.

**Contribution to the study of circulation:** Studies on the sweet potato (*Ipomoea batatas*), B. H. A. Groth (New Jersey Stas. Rpt. 1909, pp. 343–350, pls. 2).—This paper is a preliminary report of an investigation of the reversal of the water current caused by withholding water from the lower joints and supplying it to the upper ones of a sweet potato vine grown in a hothouse. A piece of the main stem with a side branch was potted and subsequently at intervals of 2 ft. the growing vine and branches were rooted in pots, and the effects of withholding water from the main stem but supplying it to the rooted subdivisions of the branches were noted.

It was found that a reversal of the water current occurred by which the entire system of the main stem and side branches was enabled to grow from water supplied to the pots in which the side branches were rooted. The roots of the main stem increased in size when in perfectly dry soil, thereby proving, so the author holds, that rooted branches of the sweet potato may, under certain conditions, help to increase the root crop of the main plant.

**On the metabolism of ripening seeds,** W. Zaleski (Bot. Centbl., Beihefte, 27 (1911), 1. Abl., No. 1, pp. 63–82).—The results are given of investigations on the metabolic changes that occur during the ripening process of seeds as influenced by light, dampness, oxygen, and temperature conditions, especially with reference to the nitrogenous compounds formed in the seeds.

**The effect of light and changes in temperature on the germination of seed and the influence of the water content of the seed in this connection,** L. Pickholz (Ztschr, Landw. Versuchswe. Österr., 14 (1911), No. 2, pp. 124–151, fig. 1).—The observations made by the author showed that the seed of *Poa pratensis* germinated normally in the dark only when heated for a time, but that when the heat was applied constantly at either 20 or 28° C., normal germination did not take place. The influence of direct sunlight was mainly due to the heat rays which brought about a temporary increase in temperature. The light rays also were observed to exert a slight influence upon germination, which is considered as possibly due to their transformation into heat. Under constant temperature conditions the seed of *Poa* did not germinate normally even in direct sunlight when the heat rays were excluded. The effect of the change of temperature was the same in different stages of maturity.

It was further observed that in general the water content of the seed was in inverse proportion to the percentage of germination. In most cases when water was driven off the germination of the seed was benefited, while an addition of water in most cases proved unfavorable, although there were some instances in which it remained indifferent and a few in which it proved advantageous.

**Photosynthesis and the production of dry matter in white and in colored light,** W. Lurmenko (Rev. Gén. Bot., 23 (1911), No. 265, pp. 1–14).—As a result of his experiments the author claims that for the production of dry matter by green plants there is an optimum light requirement, but that its absolute value is less than that which the chlorophyll apparatus needs to perform the maximum of photo-chemical work as expressed by the decomposition of carbon dioxide.
The energy of the decomposition of carbon dioxide for a green leaf in a colored light depends upon the absorption of the different colors by the chlorophyll in regard to their caloric energy. The true fixation of carbon by a plant expressed by the increase in dry matter in the course of its growth is unequally influenced by the different rays of the solar spectrum. The maximum of dry matter corresponds to the blue violet rays and not to the red rays of the spectrum. The increase in dry matter with the yellow orange rays was less than that of the red and is least with the green rays.

If photosynthesis is divided into 2 parts, then the first stage is characterized by the decomposition of carbon dioxide and the synthesis of the first organic products. The plants utilize to a great extent during this stage the red rays of the solar spectrum.

The second stage is characterized by the definite fixation of the primary organic substances elaborated in the green cells, and the plant employs for this work the blue violet rays.

Pigment formation in cultures of Azotobacter chroococcum, W. I. Omelianovskii and O. P. Ssecondova (Centbl. Bakt. [etc.], 2. Abt., 29 (1911), No. 23-25, pp. 643-650, fig. 1).—After a review of the literature on this subject, the authors give the results of their experiments on pigment formation by A. chroococcum.

It was found that certain strains of this bacterium were characterized by the formation of pigment which was more quickly produced when old, brownish cultures were used as a source of inoculating material. This pigmentation occurred best at an optimum temperature of about 30° C., under well aerated conditions, and in a dextrin agar medium to which lime carbonate had been added. The pigment is insoluble in the usual solvents, but can be dissolved in the presence of an alkali.

On the relative amount of mineral foods in soils and their relationship to plant growth, D. Dezső (Verhandl. Internat. Agropec. Konf. [Stockholm], 2 (1910), pp. 178-196).—In a study of the relationship of mineral foods to plant growth the author found that the greater the relative amount of soluble mineral foods in the soil compared to the soil moisture present, the more vigorous was the plant growth on such soils; that is, the denser the mineral food solution of a given soil, which density is dependent upon the available amount of soluble salts and on the average water content of the soil, the more food would the plants have, and therefore the more vigorously would they grow.

The retention of mineral matter by annual plants; the distribution of the fixed elements, G. André (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 11, pp. 963-967).—In previous papers (E. S. R., 25, p. 325) the author gave the results of investigations on the retention of mineral matter by annual plants and on the distribution of dry matter, total ash, and nitrogen content. In this article the distribution of the phosphoric acid, potash, lime, and magnesia in each organ is given for 5 different periods in the growth of the plant.

The distribution of the phosphoric acid was found to be more regular than that of the nitrogen, and reached its absolute maximum weight in roots, stems, and leaves at the beginning of the fruiting period, when it diminished to the end of the growth of the plant. In the fruits the phosphoric acid increased with the same rapidity as the nitrogen during the active period of maturation. The potash varied essentially the same as the nitrogen. The lime and magnesia increased in absolute weight in all the organs, but toward the close of the plant growth the weight of these 2 bases diminished in the leaves.

The relationship of organic phosphorus to amido-nitrogen and to non-proteid nitrogenous compounds in ripe seeds, A. Parrozzani (Rend. Soc. Chim. Ital., 2. ser., I (1909), pp. 205-207).—As the result of experiments with the ripe grain of maize on the relationship of organic phosphorus to certain
organic nitrogenous compounds, it is claimed that the production of amido-
nitrogen and other nonproteid nitrogenous substances is proportionate to the
amount of phosphoric acid present in the seeds, especially the phosphoric acid
of Posternak. The author believes that Posternak’s phosphoric acid is a
combination of phosphorus with inositol, that lecithin is a combination of phos-
phorus with glycerin, stearic acid, and collin (collina), and that lecithin repre-
sents the final stage by which nonnitrogenous organic substances acquire the
power of combining with nitrogen, especially with amino acids, for the synthe-
sis of albuminoid substances.

On the utilization by higher plants of various organic nitrogenous sub-
stances, M. Molliard (Bul. Soc. Bot. France, 57 (1910), No. 7, pp. 531–537).—
In the experiments here recorded on the absorption by the roots and the utilization
by the plants of organic nitrogenous compounds, the author investigated 3
main points, viz, (1) the action of various organic nitrogenous substances on
the development and production of fresh and dry matter, (2) the total nitrogen
content of plants thus grown, and (3) the formation of protein substances from
the absorbed nitrogen.

The following substances were used in the culture media in the ratio of
1:1,000 parts: Urate of sodium, aspartic acid, asparagin (1:500), glycocoll,
legumin, cyanid of sodium, amygdalin, hydrocyanic acid, leucin, tyrosin, myro-
nate of potassium, and alamin. Of these substances the first 9 were utilized by
the plants as shown by the increase in fresh and dry matter over similar plants
grown as checks. This utilization was greatest by the urate of sodium, and decreased in the order named down to leucin. Tyrosin, myronate of potassium,
and alamin were toxic to the roots. The amount of proteid nitrogen found in
seedlings grown in the presence of asparagin and glycocoll was about twice the
total nitrogen content of the ungerminated seeds.

The action of useful and injurious stimulants on the respiration of liv-
ing and dead plants, N. Ivanov (Biochem. Zischr., 32 (1911), No. 1, pp. 74–96,
fig. 1).—In continuation of previous investigations (E. S. R., 24, p. 138) the
author has carried on experiments on the action of inorganic phosphorus com-
ounds, the autolytic products of yeast cells, quinin, sodium selenate, arbutin,
and other substances on the respiration of living and dead wheat seedlings, and
on the etiolated tips of beans.

It was found that 1 and 2 per cent solutions of disodium phosphate did not
stimulate respiration in the living bean tips, but that when killed by freezing
an increased respiration was apparent, amounting to 27 per cent for the 1 per
cent solution of the phosphate and 62 per cent for the 2 per cent solution. The
increased output of carbon dioxide was at the expense of the primary anaerobic
processes. The phosphate did not produce on the dead tissues any increase of
respiration in the secondary oxidation process.

These experiments, it is claimed, furnish a new proof of the genetic connec-
tion between the primary anaerobic and the secondary oxidation stage of the
respiration processes in the higher plants. The increased carbon dioxide output
can not be ascribed to a stimulating action of the phosphates, as the increase
also occurred with dead tissues. In the experiments with yeast it was found
that the autolytic products favored principally the primary anaerobic respira-
tion stage. The quinin increased the carbon dioxide output of the living tissues,
but on the dead tissues it acted either as a poison or had no influence. The
other substances tested depressed the respiration of both living and dead
tissues.

The action of methyl alcohol and other alcohols on green plants and
1–3, pp. 53–64).—The results are given of experiments on the growth of various
plants in culture media to which certain percentages of different alcohols had been added.

It was found that phenols in general were more unfavorable to plant growth than the true alcohols of the fatty series. In most instances no vegetation was able to grow in the presence of the phenols, with the exception of a slight growth of mold which occasionally developed. Of the alcohols of the fatty series, methyl alcohol proved a good source of carbon for many bacteria and fungi, and for some green plants. Beans and peas in water cultures containing 0.5 to 1 per cent solutions of methyl alcohol made a better growth than control plants grown in only a mineral food solution. Pot plants of beans, peas, grain, etc., also showed a positive increase in growth when watered with methyl alcohol solutions.

Ethyl alcohol was able to furnish food for bacteria, but not for the higher plants.

Investigations on the effect of formaldehyde on green plants, V. Grafe (Ber. Deutsch. Bot. Gesell., 29 (1911), No. 2, pp. 19-26, figs. 2).—In continuation of a line of experiments previously reported (E. S. R., 22, p. 290) studies have been made on the effect of formaldehyde gas on green plants.

The seedlings (Phaseolus vulgaris) were grown in pots, the soil of which was prevented from absorbing any of the formaldehyde gas by a coating of Stanniol and vaseline, or of paraffin. Comparisons were made between the growth in the formaldehyde vapor without the presence of carbon dioxid and in an atmosphere containing carbon dioxid.

It was found that the formaldehyde not only acted as a stimulant but was really assimilated by the plants and changed into organic matter in the form of reducing sugar.

The nature, distribution, and effects upon vegetation of atmospheric impurities in and near an industrial town, C. Crowther and A. G. Ruston (Jour. Agr. Sci., 4 (1911), No. 1, pp. 25-55, figs. 3).—The results are given of investigations and observations made during the years 1906 to 1910 at the Manor Farm, at Garforth, and in the city of Leeds, which comprised analyses of rain-water samples and studies of the effects on vegetation of certain atmospheric impurities, such as smoke, acid waters, etc. Special attention was given to the effects of smoke-laden atmosphere upon the intensity of light, the relative assimilatory power of leaves in different localities, the effects of acid waters upon the growth of grass, and the bacteriological condition of the soils.

It was found that the atmosphere in the vicinity of a large industrial city, such as Leeds, is relatively highly charged with impurities, many of which exert a marked injurious effect upon plant growth. The rain water in such regions was found to be notably rich in suspended matters, such as chlorids, sulphates, and other sulphur compounds, nitrogenous compounds, and free acid. The suspended matters in the air impeded plant growth, not only by their deposition upon the leaves and the consequent hindrance to the free interchange of gases between the leaves and the air, but also by reducing the light intensity, which reduction in some instances amounted to fully 40 per cent of the maximum light available. The free acid present in the atmosphere was found to be detrimental to plant growth by its direct action on the leaves, and also indirectly by reducing the ammoniacal fermentation of the soil humus, and by decreasing the activity of the nitrifying and nitrogen-fixing soil organisms. In an experiment with timothy the continued application of the acid rain water produced plants distinctly poorer in protein but richer in crude fiber.

On the systematic position of Zea mays as indicated by atavisms produced by smut infection (Ustilago maydis), H. Iliris (Ztschr. Induktive
Abstam. u. Vererbungslehre, 5 (1911), No. 1, pp. 38–57, pls. 2, fig. 1).—In a general discussion of the origin of corn (*Z. mays*) as to whether it is a direct descendant of *Euchlora mexicana* or was directly evolved from some member of the tribe Andropogoneae, the author holds that the traumatisms produced in corn by smut indicate that it is descended from the Andropogoneae.

On injurious bacterial conditions in soils and on soil purification, R. Emmerich, Wilhelm Graf zu Leiningen, and O. Loew (Centbl. Bakt. [etc.], 2. Abt., 29 (1911), No. 23–25, pp. 668–683, figs. 2).—Under the head of injurious bacterial conditions in soils the authors discuss the conditions under which desulphurization, denitrification, and acid formation in soils occur, and give the results of experiments with various species of bacteria that play a rôle in these processes.

On nitrate and nitrite assimilation, O. Baudisch (Ber. Deut. Chem. Gesell., 44 (1911), No. 8, pp. 1009–1013).—The author claims as a result of his investigations that nitrate and nitrite assimilation by green plants is a light-chemical process.

International catalogue of scientific literature. R—Bacteriology (Internat. Cat. Sci. Lit., 8 (1911), pp. VIII+636).—This is in continuation of the series of catalogues of scientific literature (E. S. R., 21, p. 728), the literature indicated being mainly that of 1908. About 6,500 titles are given, of which less than 100 are to American publications.

FIELD CROPS.

[Tests of field crops], J. M. Scott (Florida Sta. Rpt. 1910, pp. XVIII+XXIV).—The experimental data reported on Japanese cane have been already noted (E. S. R., 24, p. 733).

In a test of 8 corn varieties Georgia and Rawls produced the highest average yields, 20.06 and 18.2 bu. per acre, respectively. In a test of 20 varieties of sorghum Nos. 22330 and 24130 produced the highest yields, 13.73 and 13.47 bu. per acre, respectively. The seed distributed to the farmers of the State was Gooseneck and Sumac "which have been proved to be good varieties for Florida conditions."

Two cuttings of guinea grass gave a total yield for the season of 3,759 lbs. per acre of cured hay, while Para grass after an application of $37\frac{1}{2}$ lbs. of dried blood, 75 lbs. acid phosphate, and 28 lbs. muriate of potash yielded 3,961 lbs. of cured hay per acre.

In a test of 19 sweet potato varieties White Seedling No. 15 and Sugar Yam No. 5 gave the highest yields per acre, 116.24 and 108.74 bu. per acre. Beardless barley and hairy vetch sown together for winter pasture made a better growth than (1) Appler oats and English winter vetch, (2) crimson clover, or (3) white-blooming crimson clover.

Selected velvet bean seeds from which faulty and immature seeds had been rejected produced 33.75 bu. of shelled beans per acre as compared with 28.37 bu. secured from unselected seed. On an acre used for continuous planting the yield was only 1.137 lbs. of beans in the pod or 11.37 bu. of shelled beans. The Lyon bean gave an average yield of 17.37 bu. per acre and appears to be but little different from the velvet bean in feeding value.

Among 110 varieties of cowpeas 12 "showed strong indications of being resistant to both root-knot and wilt." An acre of ground planted to kudzu in
March, 1909, and not cut for hay during that year had made a growth of 2 ft. by March 16, 1910, and of from 12 to 15 ft. by May 4.

Report of assistant botanist, J. BELLING (Florida Sta. Rpt. 1910, pp. LXXIX-XCII, figs. 6).—These pages report the results of an attempt to secure a hybrid that would combine the thin unopening hull of the velvet bean with the Lyon bean's smooth pods which do not have the objectionable stiff irritating bristles.

In 1908 velvet bean flowers were fertilized with Lyon bean pollen. The pollen parent is thought to have been grown from seed received from the Philippine Islands. All pods borne by the hybrid plants grown in 1909 had so many loose irritating hairs that there was trouble in harvesting them, and they could be shelled comfortably by hand only after the bristles had been brushed off under water.

The author presents in parallel columns the principal characteristics of the velvet, Lyon, and hybrid beans and in tables statistical data showing the standard deviation and coefficients of variation of the length, breadth, and thickness of the bean, the length and breadth of the strophiole, and the coefficient of correlation between (1) length and breadth, (2) breadth and thickness of seed, and (3) between length of seed and length of strophiole. His conclusions following this data are briefly summed up as follows:

"The hybrid plants seem to derive the color of their three upper petals, the length of the bristles on the pod, and the thickness of the seeds from the velvet bean; while the stiffness of the bristles on the pod, the opening of the pods, the length and stoutness of the pods, and the length and breadth of the seeds seem to come from the Lyon bean. The mottling on the seeds of the hybrids varies from thickly mottled, like the velvet, to unmottled with veins like the Lyon, but the hue of the colored patches is a lighter brown than on the velvet bean. Whether these characters are truly dominant can only be told when the next generation shows whether they segregate or not. The coefficients of variation in the hybrid seeds are no greater than those of the seeds of the two parent strains, except as to the mottling.

"The close agreement of the length and breadth of the hybrid seeds with those of the Lyon bean, and of the thickness with that of the velvet, may possibly be genetic, or may be due to special conditions of growth."

Progress reports are given of an investigation of the causes of the premature falling of persimmons, the sugar content of the juice of West Indian cane, and corn breeding work. Of the 5 cane varieties tested "B. 208 was the earliest and ripest cane, and its juice gave 17.3 per cent of cane sugar by the polariscope" in October, 1909. Three kinds of field corn and 3 of sweet corn were sown with the reddish yellow West Indian corn from Cuba in the hope of selecting from the second and following generations types combining good ears with the sturdier constitution of the Cuban corn, its supposed resistance to the corn worm, and its considerably greater adaptability to the climate of southern Florida.

[New Jersey experiments with field crops], F. C. MINKLER (New Jersey Stas. Rpt. 1909, pp. 43-53, pls. 4).—In a test of 3 varieties Silver King yielded 65.7 bu. of corn per acre, but in fodder yield was excelled by Boone County White with 13.2 tons. The average cost per ton of growing and harvesting alfalfa hay was $5.34 and of mixed hay $4.82. The cost of growing corn and cowpeas for silage was $2.61 per ton, while that of cutting the crop and filling the silo was $1.30 per ton.

Brief statements are also given of work with rye, wheat, oats, and peas, Japanese barnyard millet, cowpeas, flint corn, cabbages, and turnips, alfalfa, and fertilizers for silage corn and other crops.
Grass and clover seeds at Cockle Park, D. A. Gilchrist (Trans. Highland and Agr. Soc. Scot., 5. ser., 23 (1911), pp. 102–112).—Notes are given on Italian rye grass, tall oat-grass, meadow fescue, cocksfoot, timothy, red or broad-leaved clover, alsike clover, trefoil or yellow clover, and white clover. Progress reports deal with tests of grass seed mixtures and fertilizers and the production of the seed of wild white clover.

In a 3-year test, 3 out of 4 plats of grass seed mixtures showed higher average returns after the use of 10 cwt. of slag containing 200 lbs. of phosphoric acid than after (1) 10 tons of dung or (2) 10 tons of slag and 10 tons of dung.

Forage plant culture in Switzerland, A. Elofson (Secriges Utsvidesför. Tidskr., 21 (1911), Nos. 1, pp. 27–53, pls. 5, figs. 6; 2, pp. 84–92).—A report on observations made by the author during a visit to Switzerland, describing measures adopted by the Swiss government for the improvement of forage crops.

Report of cooperative variety tests and fertilizer experiments, Zealand, 1910, O. H. Larsen (Ber. Landbofor. Virks. Planteavl. Själland, 1910, pp. 404, figs. 8).—The report gives accounts of cooperative work for the advancement of agricultural crop production, conducted during 1910 by members of the county agricultural societies of Zealand. The experiments included 264 fertilizer tests and 206 trials with various agricultural crops, methods of sowing, time of sowing barley, and planting root crops. Experiments on the control of weeds and plant diseases are also reported.

Annual report of agricultural stations in charge of the deputy director of agriculture, Bengal, for the year 1909–10, F. Smith (Ann. Rpt. Agr. Stas. Bengal, 1909–10, pp. 25, pl. 1).—At Cuttack in a 3-year test of 8 fertilizer mixtures the highest jute yield followed an application of cow manure, superphosphate, kainit, sulphate of ammonia, and sulphate of magnesia. In a test of 9 different mixtures the highest rice yields followed applications of (1) cow manure, superphosphate, saltpeter, and sulphate of magnesia; (2) cow manure, superphosphate, and saltpeter; and (3) dhaincha treated as a green manure.

The author presents the results of other experimental work and the quantity of seeds distributed at Cuttack and 13 other experiment stations. Parallel columns give historical, geographical, meteorological, and soil data relating to the 14 stations.

Permanent and temporary pastures, M. J. Sutton (London, 1911, pp. VIII+144).—Full directions for growing and utilizing grasses, clovers, and certain sunry crops are accompanied by statements of the agricultural value and characteristics of 26 grasses, 7 clovers, and 6 sunry plants used for grazing, feeding, or making into hay.

The farm grasses of Ohio, C. G. Williams (Ohio Sta. Bul. 225, pp. 151–174, figs. 10).—The average annual yields in tons of hay secured during the period 1905–1910 from 8 of the 10 grasses dealt with in this bulletin were timothy 3.497, redtop 2.817, tall fescue 2.455, tall oat grass 2.247, orchard grass 2.197, meadow fescue 2.1, and perennial rye grass 1.822. Italian rye grass yielded 2.56 tons in 1910 and brome grass yielded from 1.45 tons in 1905 to 2.98 tons in 1910. Tables report in full the yields obtained, the cost of grass seed per acre, and analyses of each of these grasses. In separate discussions of the several grasses, historical information, suggestions as to rotation, seeding, harvesting, and utilization are given.

A heretofore unnoted benefit from the growth of legumes, T. L. Lyon and J. A. Bizzell (New York Cornell Sta. Bul. 294, pp. 365–374).—In the investigations reported in this bulletin it was found that timothy grown with alfalfa
or red clover had a higher protein content than that grown without these legumes. Oats grown with peas also showed an increased protein content and the hay yield of mixed oats and peas was 4,375 lbs. as compared with 3,325 lbs. of oats grown alone.

Soil that had produced alfalfa for 5 years was higher in nitrate content than soil which had grown timothy during that period, and portions of the same plats kept bare of vegetation during the summer showed similar results. Ammonium sulphate was more rapidly nitrified in alfalfa soil than in timothy soil, indicating, in the opinion of the author, an influence of the plant on conditions favoring nitrification. The increased protein content of nonlegumes when grown with legumes is also attributed to this cause. Limed soil produced alfalfa containing a higher protein content than unlimed soil, and the weed *Erygern annuus* grown on limed soil had a higher protein content when it was grown with alfalfa also.

The method used in making studies of the nitrifying power of soils is described. The results upon which the author bases his conclusions as to the relative protein content of nonlegumes when grown with and without legumes are summarized in the following table:

**Relative protein content of certain nonlegumes grown with and without legumes.**

Grimm alfalfa and its utilization in the Northwest, C. J. Brand (U. S. Dept. Agr., Bur. Plant Indus. Bul. 209, pp. 66, pls. 2).—A statement of the history and a description of Grimm alfalfa are followed by tables presenting meteorological data for Wertheim, Germany, from which locality it is supposed to have been imported, and various other localities in which it has been grown. Other tables present meteorological data for the periods and localities of the tests reported by the author. The following table briefly summarizes results obtained in some of these tests, made at the Minnesota Station:

- Total loss from all causes between the spring in which the count was made and the preceding spring, as the plants were not counted during the autumn. This is the percentage loss during these plats' second winter, the loss during the preceding season being reported just above in this table.
- Less for entire year.
- Selected by W. A. Wheeler at Highmore and Brookings, S. Dak.

The author summarizes data from sources already noted (E. S. R., 17, p. 355: 10, pp. 131, 330; 24, p. 142).

Near Tappen, N. Dak., in a test of the hardiness of 16 strains, Grimm seed from Minnesota and seed from Chinook and Billings, Mont., gave stands 90 per cent perfect, and seed from Clearwater, Nebr., and Lawrence, Kans., 85 per cent perfect stands. The plats were seeded in May, 1905, and the stand estimated in September, 1906, at the close of the fifth season. "Many of the strains included in this experiment were duplicated in the experiments at Dickinson, N. Dak., and there is a general agreement in behavior as to cold resistance at the 2 places." The Eifeler "cern, from a point in Germany near the home of Grimm alfalfa, was included in this test. It is practically identical in its botanical characteristics with Grimm alfalfa, but its physiological behavior in the Tappen test was altogether different, as the stand September, 1909, was only 5 per cent perfect. All the plats were cut for seed in August, 1909, and the best, including the Grimm and Montana strains, yielded about 2½ bu. per acre. "The work at Tappen indicates that in the drier portions of North Dakota farmers who desire to grow alfalfa, and who can not obtain Grimm seed, should use either Montana or Nebraska strains."

At Fayetteville, N. Y., a similar series of alfalfa varieties and strains was tested. In 1906 Grimm gave a total yield of 7,450 lbs. as compared with 3,340 lbs. for Turkistan. In 1907 Grimm yielded 5,440 lbs. as compared with 4,820 lbs. from Utah nonirrigated seed No. 12409 and 2,300 lbs. from Turkistan. These figures indicate, in the author's opinion, that Grimm can be depended upon for its hay-yielding capacity as well as on account of superior hardiness.

Experiments at Bozeman, Mont., indicate that the Grimm alfalfa "is decidedly the best for many sections of the State."

At Indian Head, Saskatchewan, Canada, among 9 alfalfas sown in May, 1905, S. P. I. No. 12901 (Carver County, Minn., Grimm) had about 95 per cent of the stand remaining in the spring of 1906 as compared with 60 per cent of S. P. I. No. 11211 from Samarkand, Turkistan, and 50 per cent each of S. P. I. Nos. 13291 and 13230. The seed for the last 2 samples was grown at Fayetteville, N. Y., and Milburn, Nebr., respectively. During the period 1904-1909, 6 alfalfas were tested at Indian Head. In 1906 Grimm produced at 2 cuttings 7717°—No. 5—11—4
7.112 lbs. as compared with 3,740 lbs. for Turkestan. In 1909, however, it was slightly exceeded by S. P. I. No. 13291. In 1906 Minnesota Grimm was the only variety not injured by frost, and in 1908 the superintendent of the Indian Head experimental farm stated that from the first of the experiments "Grimm alfalfa has never been winter or spring killed in the least."

The author reports the experiences of numerous farmers who have had good results with Grimm alfalfa, discusses its forage and seed producing capacity, general behavior, temperature relations, and drought resistance, and summarizes its behavior, stating that in the North its effective growth begins earlier and continues later than that of any other strain successfully cultivated there, and that it has unusual vigor, earliness, and yielding power in seed production. It is up to the average in drought resistance and in Minnesota usually produces 3 good hay crops and enough additional growth for pasture or hog feed.

Suggestions for beginners in alfalfa culture, A. T. Wlancio (Indiana Sta. Circ. 27, pp. 7).—Directions are given for producing and using alfalfa in Indiana.

Barley: Growing the crop, H. B. Derr (U. S. Dept. Agr., Farmers' Bul. 443, pp. 38, figs. 17).—The author presents an illustration of a new hybrid awnless barley (E. S. R., 24, p. 335), which he calls Arlington Awnless. The principal topics dealt with in the text of the bulletin are the origin and history of barley; its botanical characters; its introduction into the United States; its soil, climatic, and moisture requirements; and directions for improving, producing, and storing the crop.

The author cites experimental data from sources already noted, and reports variety tests conducted at a number of points in the barley-growing area. The yields of the more productive varieties are stated in the following table:

**Tests of barley varieties.**

*a Is the legal weight of hulled barley is 60 lbs. per bushel, and that of hulled barley only 48 lbs. per bushel, the yields in pounds of hulled barley in some cases in these tests were greater in case of certain hulled varieties although the number of bushels reported for the hullless varieties were smaller.

Bouloaua fiber, K. Braun (Pflanzer, 7 (1911), No. 1, pp. 22-26).—This article describes the plant *Gomphocarpus semilunatus* from which bouloua
fiber is derived, and discusses its distribution, methods of culture and harvesting, and uses. A chemical analysis of the fiber is also presented. It is believed that this fiber may be used as a substitute for flax fiber.

Variety tests with red clover, 1898-1910, E. Lindhard (Tidskr. Landbr. Plantavl., 18 (1911), No. 1, pp. 1-95).—The author reports the results of a continuation of the study of varieties of red clover conducted at Danish experiment stations already noted (E. S. R., 16, p. 37).

Tests of over 400 samples of red clover of different origin were made at 6 experiment stations during 1898-1910. The types of clover of different countries are dealt with on the basis of the results obtained in these and earlier trials, covering in all variety tests with about 2,000 samples of red clover seed from different parts of the world.

The cultivated form of red clover, according to the author, has 2 main varieties, late and early red clover, which are often cultivated side by side within the same district of Denmark. The typical late red clover, as a rule, grows stems only once during the summer and gives therefore only one cutting. Early red clover grows stems several times the same summer and gives several cuttings. It blooms 10 to 20 days earlier than late red clover. The latter form is found in countries where the winter is most severe and the summer shortest, like Norway, most of Sweden, Finland, Northern Russia, and Siberia.

Most of the 4,400,000 lbs. of clover seed which Denmark imports annually is the early variety. The best seed of early red clover comes from Russia, Bohemia, and Holstein, in the author's opinion, while the late clover seed is imported from Sweden, Norway, Silesia, and Bohemia. The seed of the late clover grown in Denmark yielded considerably better than the imported seed. This form is especially adapted for cultivation with timothy and other late blooming grasses, or in pure stand. Under these conditions it gives, as a rule, larger hay crops and does better in cold and moist ground than the early red clover.

How to grow more and better corn, A. Goss, A. T. Wiancko, and J. B. Abbott (Indiana Sta. Circ. 25, pp. 36, figs. 10).—A discussion of the status of corn growing in Indiana and directions for the production of the crop accompany statements of the results of fertilizer and cropping system tests.

After 20 years' continuous cropping to corn the yield on the fertilized plats was 22.2 bu. less and on the unfertilized plats 35.1 bu. less than in 1889, the first year of the test. In cropping to corn and wheat the decreases during the same period were 2 and 24.6 bu. per acre, respectively, while in a corn, roots, oats, wheat, and clover and grass rotation increases of 15 and 2.7 bu. per acre occurred on the fertilized and unfertilized plats, as compared with the yields 20 years earlier. After (1) a corn, oats, wheat, and clover rotation, and (2) a corn, oats, wheat, and clover and grass rotation, the yields on the unfertilized plat had greatly decreased, and those on the fertilized plat had considerably increased.

The relation of live stock to soil fertility is discussed. The average gain secured from an average application of 4.5 tons of manure per acre on the last 2 crops in 5 different rotations was 17.1 bu. per acre. Tests in 5 representative counties resulted in an average gain of 6.6 bu. per acre at an average cost of $1.11 per acre for fertilizers or $1.39 return for every dollar invested in fertilizer. This amount was secured after the use of phosphorus and potassium and is much greater than that secured after the application of a complete fertilizer, or of (1) nitrogen and potassium, or (2) nitrogen and phosphorus. A table states also the calculated effect and value of each element by difference.

In Starke, Henry, Newton, and Madison counties the average yield secured on check plats was 36.4 bu. per acre as compared with 60.4 bu. after an
application of 200 lbs. of muriate of potash, 61 bu. after an application of 200 lbs. of muriate of potash and 300 lbs. acid phosphate, and 61.4 bu. after an application of the last-named mixture and 100 lbs. of dried blood in addition. Separate papers deal with corn insects (by J. Troop) and corn smut (by A. G. Johnson).

Annual report of the Kalimpong Demonstration Farm for the year 1909-10, P. Goodwin (Ann. Rpt. Kalimpong Demon. Farm [Bengal], 1909-10, pp. II+21, maps 2).—In a variety test the locally grown maize produced yields about 7 times as great as those from Jaunpur maize. On terraced land corn produced about one and a half times and buckwheat about twice as great yields as were secured from terraced land. The difference is attributed to the newly exposed subsols which constituted half of each terrace.

Cotton growing in the Cape Province, A. Van Ryneveld (Agr. Jour. Union So. Africa, 1 (1911), No. 3, pp. 410-412).—Four samples of Egyptian Abassi cotton all showed weakness of fiber, while the Mit Affi sample examined was fairly strong. A full report for each sample is given as to weight, color, strength, diameter of fibers, and commercial valuation.

General report of the cotton commission, 1910 (Rap. Gén. Com. Coton [Egypt], 1910, pp. 36, table 1, pls. 2).—This report, presented to the Egyptian government, describes various factors entering into cotton culture, including irrigation, precipitation, soil, degeneration, impurity, and variation in the plant, crop rotations, fertilization, and the prevention of insect injury. Notes are also given on the agricultural organization, the experiment stations, and the work of special agricultural committees in Egypt.

Report of field trials on the manuring of mangels, 1907-1910, T. Milburn and R. C. Gaut (County Council Lancaster, Ed. Com., Apr. Dept., Farmer's Bul. 19, 1911, table 1, pp. 8).—In a 4-year test of 7 different applications of natural and artificial fertilizers on various farms, the highest average yield of mangels followed the use of a mixture of 15 tons of farmyard manure, 2 tons of nitrate of soda, 3 cwt. superphosphate, 3 cwt. kainit, and 1 cwt. salt. The nitrate of soda was applied “$\frac{1}{2}$ as 2 top-dressings.” An almost equally high yield of mangels and a considerably higher profit followed the application of a mixture similar in every respect except that the salt and one-half the nitrate of soda were omitted.

As a result of fertilizer tests the author concludes (1) that increasing the application of farmyard manure from 15 to 25 tons did not materially increase the crop; (2) that incomplete artificial fertilization was less profitable than complete fertilization; (3) doubling the amount of nitrate of soda in a complete mixture greatly reduced the profit; and (4) the use of 1 cwt. of salt gave a good return.

Millets of the genus Setaria in the Bombay Presidency and Sind, G. A. Gamme (Mem. Dept. Agr. India, Bot. Ser., 4 (1911), No. 1, pp. 8, pls. 5).—Descriptions and illustrations are given of Setaria glanca and of S. italica and of 3 varieties of the latter.

Potato spraying experiments in 1910, F. G. Stewart, G. T. French, and F. A. Sirrine (New York State Sta. Bul. 338, pp. 115-151, pl. 1, dgm. 1).—This bulletin gives the results of the ninth year’s work in the 10-year series of potato spraying experiments begun in 1902, together with a summary for the entire period. Earlier results have already been noted (E. S. R., 19, p. 447; 20, p. 1043; 23. p. 449.)

During 1910, 19 separate experiments were conducted along the same lines as in previous years. “At Geneva 6 sprayings increased the yield 63 bu. per acre and 3 sprayings increased it 22 bu. Flen beetles, early blight, late blight, and rot were all factors in the experiment. The benefit from spraying was
scarcely noticeable until after September 2. At Riverhead the gain due to 5 sprayings was 19 bu. per acre and to 3 sprayings $\frac{3}{4}$ bu. The plants suffered from drought and were slightly injured by flea beetles, aphids, and early blight, but there was no late blight or rot.

"In 12 farmers' business experiments, including 218 acres, the average gain due to spraying was 10.1 bu. per acre; the average total expense of spraying, $\$1.04$ per acre; and the average net profit, $\$4.39$. In 3 of the experiments spraying was unprofitable."

Five volunteer experimenters averaged 68 bu. per acre in the gains reported. Early blight was not destructive and little injury to foliage resulted from a late outbreak of late blight, although it caused considerable loss from rot. Colorado beetles, flea beetles, and tip burn were the chief source of trouble to potato foliage in 1910.

**Dry weather tests potato spraying**, F. H. Hall (New York State Sta. Bul. 338, popular ed., pp. 3-8).—This is a popular edition of the above.

**Better grain-sorghum crops**, C. R. Ball (U. S. Dept. Agr., Farmers' Bul. 448, pp. 36, figs. 12).—This bulletin gives "the best known methods of improving the grain-sorghum crops on the farms where they are grown." It deals with the topography, soils, climate, and agricultural development of the grain-sorghum belt, the history, uses, and statistics of the crop, and the methods of improving it in drought resistance, earliness, dwarfness, and productiveness. Earlier papers on the same subject by this author have already been noted (E. S. R., 22, p. 729; 23, p. 140; 24, p. 734).

**Transmission of the nitrogen content in the sugar beet**, J. Urban (Ztschr. Zuckerindus. Böhmen, 35 (1911), No. 8, pp. 443-450).—The studies made by the author indicated that the nitrogen content of the sugar beet may be transmitted in a manner similar to the sugar content. The nitrogen content of the plants was not always in direct correlation with the sugar content. The author suggests that in improving the sugar beet by means of breeding, the nitrogen content as well as the sugar content should be taken into consideration, as this is a step in the direction of securing greater purity in the juice.

**Wheat cultivation in tropical Africa** (Agr. Jour. Mozambique, 1 (1911), No. 1, pp. 9-13).—A brief statement of the progress made in wheat cultivation in British East Africa is followed by a report of the results of commercial valuations and data as to the composition of samples of wheat grown in different parts of the world.

The results of chemical analyses are summarized in the following table:

*Gluten and gliadin contents of wheat grown in various countries.*

Statistical investigations of structural variation in cereal plants, Quante (Landw. Vers. Stat., 74 (1910), No. 1-2, pp. 121-162, fig. 1).—The statistical method and its application is discussed and examples are given showing how different factors, such as length of spike, length of stem, weight of kernel, and others are treated. The author states that for the exact description of measurable factors in cereal plants the average as determined from a single series of
individuals of this particular variety or strain is inadequate, but on account
of the asymmetrical variations in individuals from the average values these
variations as well as the average values should be taken into consideration in
arriving at the most probable value of a certain factor. The author observed
that when careful selection is practiced in plant breeding, symmetrical varia-
tions occur.

Laund. Plantteur, 17 (1910), No. 5, pp. 732-770).—This thirty-ninth annual
report of the seed-control station gives the usual summary data of results
obtained in the work of the station during the year ended June 30, 1910. Dur-
ing the year 7,604 samples of seeds were examined.
The Lom seed drill and older forms of seeders, S. Hasund (Tidsskr. Norske
Laundbr., 18 (1911), No. 2, pp. 69-88).—The article describes an old seed drill
originating in one of the interior mountain districts of Norway and used there
until recently. Its history and possible relationship to early English seed drills
are traced.

HORTICULTURE.

Report of the botanical department, B. D. Halsted et al. (New Jersey
Stas. Rpt. 1909, pp. 269-313, pls. 26).—The plant-breeding studies of the de-
partment (E. S. R., 22, p. 140) were continued. The leading kinds of plants
under observation were beans, sweet corn, eggplants, peas, peppers, squashes,
and tomatoes. Crosses and hybrids among each of these vegetable fruits were
studied and are here discussed.

In the work with beans, which is reported separately by E. J. Owen, especial
attention was paid to the series of crosses between mottled and white limas.
The hybrids between snap beans and the scarlet runner were further studied
and a large number of attempts to hybridize the snap and lima species are
under way.

Crosses between standard sorts of sweet corn and typical western field
varieties were tested by a number of cooperators throughout the State and
elsewhere. The results indicate that the added vigor of the field parent was the
probable factor that saved these crosses from destruction through drought that
came to the early, ordinary sweet sorts. The crop of sweet field corns was good
and the quality of the grains excellent. The behavior of the sweet corn crosses
when the color of the grains is different was also studied. A practically solid
flinty ear of the Malamow variety grown upon poor soil in 1908 was planted
where the soil approaches a garden condition with the general result that there
was about an equal number of the flinty and the sweet grains in the whole lot of
ears. In some instances the flintiness or its absence seemed to indicate a plant
character, since in some ears the sweet grains are the rare exception and in
others the flinty ones are scarce. The authors suggest that the drifting of the
original sweet corn may have gone far enough toward a true flinty corn so that
the starch-forming quality becomes a Mendelian factor when bred with those
gains that are more sweet than flinty; that is, the flinty grains in an other-
wise sweetish ear may be due to fertilization by pollen bearing the starch-
forming power.

Crosses between the American kinds of eggplants were under observation.
The general details of the work of developing an edible sort out of the hybrid
between the American and Chinese species are given.

Owing to the death of N. D. Shore the work with peas, peppers, and squashes
was interrupted and is only partially reported on. A noticeable result of fer-
tilization within the plant among squashes was the feebleness of the vine
followed by failure of the crop. The crosses are discussed relative to variations in shape, weight, color, and shell. The principal phases discussed in connection with the blend crosses of peppers are type of foliage and range of leaf forms, position of the fruits, seedless fruits, and secondary pistils in peppers.

Determinations of the number of seed cavities of several varieties of tomatoes show that this characteristic is fairly constant when the normal number of seed cavities is 2 or 3, as in the smaller sorts, such as Currant, Cherry, etc. It is quite variable on the other hand in the large, flat, and irregular kinds, such as Ponderosa. Crosses of the smaller and larger fruited sorts resulted in a great variety in number of seed cavities.

A number of hybrid forms were studied in the ornamental border. Of these the carnation-pink hybrids are particularly promising. A hybrid of *Hibiscus manihot* upon the okra (*H. esculentus*) was remarkable for its extreme vigor, large size, and strong blooming tendency, and may give promise as an ornamental annual.

The variations in the following wild plants are discussed and illustrated: Dandelion, shepherd's purse, mandrake, catmint, and the heads of the oxeye daisy. Observations of the velvet leaf (*Acutelion abietol*) were made on the relation of position upon the plant to the number of seed vessels, from which it appears that the fruits situated upon the main stem or near it and consequently better nourished have the greatest number of seed vessels.

Meteorological data as to rainfall, temperature, and sunshine during the growing season for the past 21 years are included.

**Report of the horticulturist, M. A. Blake and A. J. Farley** *(New Jersey Stats., Rpt. 1909, pp. 79-99, pls. 4).*—This comprises a progress report on the peach investigations being conducted at High Bridge and Vineland and the greenhouse investigations with carnations and roses (E. S. R., 22, p. 141), together with some additional data on the long-continued fertilizer experiments with cherries, and brief descriptions of a number of newer varieties of strawberries tested during the year. Experiments in dipping peach trees to control the peach root aphids are noted on page 462 of this issue.

In connection with the peach investigations at Vineland, measurements are being made each spring of the amount of annual growth made by the trees. These data for the seasons of 1907 and 1908 are here tabulated. A striking difference in the amount of injury to the young trees by wind and rain was noted with the various varieties. Generally speaking the varieties of the Persian group type sustained severe injury to the more tender leaves, while varieties of the North China type were but slightly injured. The peach leaf curl caused much damage in private orchards in the vicinity of High Bridge during the spring of 1909. The trouble was effectively controlled in the station orchard, however, by a thorough spraying with lime-sulphur, when some Elberta trees left unsprayed as a check were quite seriously affected. The variety Mountain Rose was only very slightly affected, even when unsprayed. The failure of lime-sulphur to control the curl in a number of cases is attributed to imperfect preparation of the mixture or a lack of thoroughness in its application.

In the fertilizer experiments with cherries which were started in 1896, all the plats have received an annual application of equal parts of ground bone, muriate of potash, and acid phosphate at the rate of 500 lbs. to the acre and certain plats have received an additional annual dressing of 150 lbs. of nitrate of soda since 1900. The nitrate of soda plats have yielded a larger quantity of fruit, and it is believed that this increase will be more marked as the trees grow older and require more nitrogen.
Home vegetable gardening, F. F. Rockwell (New York, 1911, pp. 262, pls. 63, figs. 4).—This is presented as a complete and practical guide to the planting and care of all vegetables, fruits, and berries worth growing for home use.

Is the hull-content of peas a variety characteristic? H. Tedin (Sveriges Utsändesför. Tidskr., 21 (1911), No. 2, pp. 72–77).—The conclusion of Fruwirth that small peas have higher percentages of hull-contents than large ones was corroborated by the author. This refers only to comparisons of plants of the same variety, however, and not to comparisons of different varieties with one another. An account is given of the author’s investigations of the above question, including a summary in German.

Newer varieties of strawberries and cultural directions, O. M. Taylor (New York State Sta. Bul. 336, pp. 45–77, pl. 1, figs. 3).—In continuation of previous variety tests of strawberries (E. S. R., 20, p. 940) this bulletin contains a report on 50 varieties, many of them recent introductions, which fruited on the station grounds in the years 1909 and 1910. Suggestions are also given relative to the cultural treatment of strawberries. The data in the variety descriptions include the source of the plants tested, brief historical notes, characteristics of plant and fruit, and the apparent value as shown under the conditions at the station.

Owing to the late spring frosts it is impossible to grow early blooming varieties in some parts of the State. Three of the earliest blooming varieties described, however, Mascot, Parcell Early, and Superior, are considered of sufficient merit in other characters to be worthy of a test, even in the colder sections of the State. Of the 50 varieties tested, 38 were discarded. Among the 12 remaining varieties are Early Ozark and Battenburg, which were unusually productive, and Deacon, a brief flowering midseason variety of high quality, as well as Mascot and Parcell Early above mentioned.

Statistical summary of the California raisin industry, 1873–1910, G. Robertson (1911), pp. 4).—This is a statistical review of the raisin industry in California, which is supplementary to a paper read at the California State Fruit Growers’ Convention, December, 1910.

Orchard heating in Indiana, W. M. Walton, Jr. (Mo. Weather Rec., 39 (1911), No. 1, p. 29).—The author briefly describes his results in the use of oil heaters during the spring of 1910. The results as a whole indicate that whereas orchard heaters may prove beneficial under normal conditions, they are of little value in the presence of continued high, northwest winds combined with freezing temperature.

Protecting trees from rabbits, J. C. Cunningham (Kansas Sta. Cirr. 17, pp. 4, figs. 4).—The author here briefly discusses the protection of trees by trapping, poisoning, and the use of repellents. Directions are given for the construction and use of a barrel trap and for a box trap that is said to have been used with remarkable success. A spray made of buttermilk and common stove soot in the proportion of 1 gal. of the former to ½ lb. of the latter, boiled for a period of 20 minutes, is said to have proved quite satisfactory as a repellent.

Manufacture and storage of homemade solutions, J. E. Harris (Michigan Sta. Tech. Bul. 6, pp. 9–15).—For the purpose of gaining information relative to the manufacture and storage of homemade lime-sulphur solutions, studies were made of the effect of lime and of magnesia on the composition of the solution, together with the effect of storing the solution in contact with the sedi-

---

ment, and the effect of reheating the solution before using. The results, which are presented in tabular form and discussed, are summarized as follows:

"If formula 50:100:50 or 60:125:60 or any other formula providing for an excess of sulphur is to be used, the lower the amount of magnesia in the lime used, the greater the amount of sulphur to go into solution. If an analysis of the lime used is available, an amount of lime should be used so that there shall be twice as much sulphur as calcium oxid. It is only in this way that a maximum amount of sulphur can be made to dissolve. There is no particular advantage to be gained by filtering the lime-sulphur solutions before storing. While there is a slightly greater dropping off in the total sulphur in the unfiltered solution than in the filtered, there is a smaller decrease in the sulphid sulphur in the unfiltered than in the filtered, provided an excess of sulphur has been used in the manufacture of the solution. In those solutions, in the manufacture of which an excess of sulphur has been used, only a very slight increase in the amount of total sulphur in solution is observed when the solution is reheated before using. This increase is not sufficient to pay for the cost of such an operation."

Manufacture and storage of lime-sulphur spray, A. J. Patten (Michigan Sta. Circ. 16, pp. 69-77).—A popular presentation of the above.

Spraying apples, A. Dickens and T. J. Headlee (Kansas Sta. Circ. 15, pp. 8).—This circular points out the value of proper spraying and the methods of conducting it. A more complete account is contained in Bulletin 174, previously noted (E. S. R., 25, p. 137).

Practical studies of the evaporation of fruits, E. Rabaté (Prog. Agr. et Vit. (Ed. l’Est-Centre), 32 (1911), Nos. 17, pp. 519-527; 19, pp. 585-596; 23, pp. 729-736, figs. 23).—A number of fruit evaporators of different types and using different kinds of fuel were tested at Villeneuve-sur-Lot, France, in 1910. The present study discusses the construction of the evaporators, describes the principal types, and gives data on the results secured with each kind.

The economic climatology of the coffee district of Sao Paulo, Brazil, R. De C. Ward (Bul. Amer. Geogr. Soc., 43 (1911), No. 6, pp. 428-445, map 1).—This paper deals with certain climatic aspects of coffee cultivation and of its preparation for market which presented themselves during a summer trip to Brazil undertaken in connection with a study of the economic climatology of the Brazilian coffee district.

Carnations, picotees, and pink, T. W. Sanders (London [1910], pp. 136, pls. 17, figs. 44).—A practical guide to the cultivation and propagation of border, perpetual, and other carnations, picotees, garden and alpine pinks, Sweet Williams, etc., including lists of varieties and a description of the various pests and diseases thereof.

Garden art, M. Fouquier (De l’Art des Jardins. Paris, 1911, pp. X+254, pls. 57, figs. 331).—This consists of a pictorial and historical account of the evolution of garden art in France, in which the author has aimed to present by way of a monument to the national garden art as complete a series as possible of old sketches and of more recent views taken during the period from the fifteenth to the twentieth centuries. Although the various periods are touched upon in the historical text, special emphasis is placed upon that period at the end of the Renaissance, when the French style became separated from the Italian conception. In addition to the general historical account the garden decorations of the various periods are discussed, together with the renovation of French gardens during the nineteenth and twentieth centuries.

Some notable gardens of other European countries are also pictured and discussed.
The landscape gardening book, Grace Tabor (New York, 1911, pp. 180, pls. 62, figs. 13).—In this popular work the avowed aim is to set down the simple laws of beauty and utility which should guide in the development of all grounds.

The successive chapters discuss utilizing natural features, the style of a garden, getting into a place, vines as harmonizers, vistas good and bad, boundaries, entrances and gateways, deciduous trees, evergreen trees, the use of shrubs, the place of flowers, winter and the garden, the vegetable garden beautiful, garden structures, garden furniture and accessories, and planting and general care.

Town planting and the trees, shrubs, herbaceous and other plants that are best adapted for resisting smoke, A. D. Webster (London and New York, 1910, pp. 111, pls. 10).—The cultural directions, together with lists of plants, given in this book are based upon the author’s experience in caring for the grounds of many public buildings in several of the worst smoke-infested parts of London.

FORESTRY.

Schlich’s manual of forestry.—III. Forest management, W. Schlich (London, 1911, vol. 3, 4. ed. rev., pp. X+463, figs. 59).—A treatise on forest management which is divided into the following general parts: Forest mensuration, forest valuation, the foundations of forest management, and preparation of forest working plans.

The successive chapters in part 1 discuss instruments used in forest mensuration, measurement of felled and standing trees, determination of the volume of whole woods, the age of trees and woods, and determination of the increment. Part 2 discusses matters preliminary to forest valuation, valuation of forest soil, of the growing stock, and of the whole woods or forests, determination of the rental of forests, and the financial results of forestry. Part 3 treats in detail of the increment, the rotation, the normal age classes, the normal growing stock, the normal yield, and relations between increment, growing stock, and yield. The discussion on the preparation of forest working plans in part 4 takes up the collection of statistics, division and allotment of the forest area, determination of the method of treatment, determination and regulation of yield, control of execution, and renewal of working plans.

Several appendixes are given containing tables and data of use in forest management.

New view points in silviculture, R. Zon (Forestry Quart., 9 (1911), No. 2, pp. 205–218).—A review of H. Mayr’s last book on silviculture (E. S. R., 20, p. 943) with special reference to the discussion of climatic factors determining the existence of forest regions. On the basis of the average temperature, air humidity, and precipitation during the vegetative period, as well as on the basis of the annual temperature, the dates of occurrence of the first and last frost, and the absolute minimum temperature, Mayr established several forest regions or zones for Europe, America, and Asia, each zone being characterized by tree species having about the same climatic requirements. The different zones are here arranged in tabular form for ready comparison.

Forestry and the lumber business, J. E. Rüdes (Forestry Quart., 9 (1911), No. 2, pp. 195–204).—The author points out the direction which the development of forestry in this country should take to be of assistance to the lumber business as a whole.

The importance of the seed source question for the breeding of healthy plants in forestry, Herrmann (Vorträge Pflanzenschutz, Abt. Pflanzenkrank. Kaiser Wilhelms Inst. Landw. Bromberg, 1911, No. 2, pp. 1–22, fig. 1).—A
study of the results of various European tests of forest seed from different countries in which the author points out that diseased conditions among forest stands may often be attributed to the use of seed procured from a climate and under conditions dissimilar to the climate and conditions where the stand is to be established.

Comparative soil moisture determinations in the litter experimental areas of the pine forests in Wiener-Neustadt, R. Wallenböck (Centbl. Gesam. Forstw., 37 (1911), No. 5, pp. 197-209).—In connection with the litter experiments which have been conducted in pine forests for a number of years under the direction of the Mariabrunn Forestry Station, Böhmerle found that a moss cover as compared with annual raking was unfavorable for regeneration by seeding (E. S. R., 20, p. 945) and also appeared to retard the growth of the trees during a dry season (E. S. R., 24, p. 445). Following up these investigations the author conducted soil moisture determinations of the experimental areas in the years 1909 and 1910. The results are presented in detail.

The most important variation between the water behavior in the moss-covered soil and in the annually raked soil was the more rapid drying out but at the same time quicker restoration of water in the raked area. In a dry year the raked area can take up water from the light summer rains, whereas the moss-covered area conserves the water for a short time only and prevents the light showers from reaching the underlying soil.

In connection with the results secured by Böhmerle, the author concludes that the harm done by a moss cover during dry years is far greater than the benefit derived through the greater amount of water stored in wet years.

The white pines of Montana and Idaho: Their distribution, quality, and uses, F. I. Rockwell (Forestry Quart., 9 (1911), No. 2, pp. 219-231).—A general discussion.

Memorandum on teak plantations in Burma, F. A. Leete ([Indian] Forest Bul. [n. scr.], 1911, No. 2, pp. 21, dyms. 4).—This memorandum summarizes the data that were available up to 1909 relative to the growing stock in teak plantations in Burma. The conclusions arrived at are embodied in the form of a series of curves, and a tabular summary illustrates the relation between age, girth, number of stems and height for fully stocked plantations in which thinnings are started as soon as required and are repeated every 10 years.

Note on the relative strength of natural and plantation-grown teak in Burma, R. S. Pearson ([Indian] Forest Bul. [n. scr.], 1911, No. 3, pp. 9, pl. 1).—Pieces of both kinds of teak of similar dimensions and containing approximately an equal amount of moisture were selected, both sets of tests being carried out with the same machine.

The results obtained for both classes of timber were very similar, and it is concluded that in as far as the wood tested is concerned, there is little difference in the strength of natural and plantation-grown teak. Although in the test for the coefficient of transverse strain the natural-grown wood has proved superior in strength to the artificial product, the strength of the latter is sufficiently high.

The culture of Hevea in the Malay Peninsula, P. J. S. Cramer (Proc. Agr. Soc. Trinidad and Tobago, 11 (1911), No. 1, pp. XV+130, pls. 25, figs. 24).—This is an English translation of Bulletin 25 of the Suriname Department of Agriculture (E. S. R., 24, p. 43).

Silvicultural treatment of abandoned pastures in southern New England, P. T. Coolidge (Forestry Quart., 9 (1911), No. 2, pp. 235-261, pls. 2).—Suggestions are given relative to the silvicultural treatment of various types of brush on old pastures.
Report on timber conditions, etc., along the proposed route of the Hudson Bay Railway, J. R. Dickson (Dept. Int. Canada, Forestry Branch Bul. 17, 1911, pp. 27, pl. 1, figs. 5).—This embraces the results of an inspection made under the direction of the Forestry Branch of the Canadian Department of the Interior. It describes the district covered and gives the details of location and quantities of timber.

Rocky Mountains Forest Reserve—Report of boundary survey parties, G. H. Edgecomb and P. Z. Caverhill (Dept. Int. Canada, Forestry Branch Bul. 18, 1911, pp. 27, pl. 1, figs. 1).—This consists of reports of forest surveys conducted on the eastern slope of the Rocky Mountains in 1910 for the purpose of determining the line of the eastern boundary of the Rocky Mountains Forest Reserve.

A self-registering caliper for measuring trees, Wild (Forstw. Centbl. n. ser., 33 (1911), No. 6, pp. 365–368, figs. 2).—A self-registering caliper, which is said to have been used successfully in measuring a number of species of trees, is here illustrated and described.

Multiple volume table, L. Crowell (Forestry Quart., 9 (1911), No. 2, p. 262).—A form is given for a multiple volume table to be used as an aid in computing the total volume of any area in which the trees are tallied by diameters and height classes. The multiple table is compiled from a volume table of the species estimated.

Wood utilization in 1909 (Bol. Min. Agr., Indus. e Com. [Rome], 9 (1910), Scr. A, No. 20, pp. 873–881).—This consists of a statistical summary for the various Provinces and districts of Italy relative to the quantity and value of construction and industrial woods, firewood, and charcoal wood used from the state and private forests in 1909.

Seasoning wood by electricity, A. Halstead (Daily Cons. and Trade Rpts. [U. S.], I, (1911), No. 149, p. 1373).—This consists of a brief description credited to a British technical paper concerning a new process of seasoning wood by electricity in France.

"A large tank is filled with a solution containing 10 per cent of borax and 5 per cent of resin, with just a trace of carbonate of soda. In the bottom of the tank is a lead plate which is electrically connected to the positive pole of the dynamo. The timber to be treated is stacked on this plate, and when the tank has been filled another plate is superimposed and connected to the negative pole of the dynamo. When the current is switched on it passes through the stack of wood between the 2 plates and in its passage it is said to drive out the sap in the timber and deposit borax and resin in its place, completely filling up all pores and interstices. When the process is completed the timber is removed and dried, after which it is ready for use. It is claimed that the timber submitted to this treatment, no matter how green it may be, becomes completely seasoned."

Forest products of Canada, 1909.—Tan bark and tanning extract used, H. R. MacMillan (Dept. Int. Canada, Forestry Branch Bul. 20, 1911, pp. 6).—This is a statistical review based upon information received from 67 tanneries and representing about 90 per cent of the vegetable tannin consumption in Canada. The total value of all the vegetable tanning materials used by Canadian tanneries in 1909 was $1,126,004.

DISEASES OF PLANTS.

Report of plant pathologist, H. S. Fawcett (Florida Sta. Rpt. 1910, pp. XLV–LXV, figs. 1).—The work of the year consisted mainly of investigations of the diseases of citrus trees, including stem-end rot, gummosis, scaly bark,
scab, silver scurf, and buckskin. Studies were also made of the red rot of sugar cane (*Colletotrichum falcatum*), of the spore stages of the brown fungus of the whitefly, which is described as new under the name of *Eugritta webberi* (E. S. R., 23, pp. 655, 758), and of a species of scaly fungus from *Lecanium* on *Pinus teda*.

The stem-end rot is a disease only recently observed on nearly all varieties of citrus fruits in Florida, but is now reported from 20 localities with its focus of infection in Volusia, Lake, and Orange counties. It has caused damage ranging from 5 to 30 per cent of the fruit in infected groves. The fruit first softens and becomes slightly depressed around the stem end without any change in the color of the rind. The rot proceeds inward along the fibers of the rind, and then outward into the pulp cells. At first there is no discoloration of the rind and pulp, but as the softening continues the rind turns a dull brown and the rag and pulp cells disintegrate, causing the entire fruit to become soft and mushy. The rot usually occurs on full-sized ripening fruit after it has dropped or has been picked, but may begin while the fruit is still on the tree. It also develops on fruit which is apparently perfectly sound when packed. Pure cultures have been isolated from the interior of diseased grapefruit, sweet and sour oranges, and from tangerines. Inoculation tests with pure cultures and with pieces of diseased tissue produced typical stem-end rot in the sound fruit, mainly of oranges, after an incubation period of about 2 weeks. These inoculation experiments showed that under laboratory conditions the infection of sound oranges may occur not only through the cut ends of stems up to 3 in. long, but also through the epidermis of the fruit and through the calyx, and that infection of oranges and lemons may occur in water either from cultures, pieces of diseased orange tissue, or infected soil.

A description of gummosis and distinctions between it, scaly bark, and foot rot are given, and the following methods of treatment are suggested: Either scrape off the diseased bark and paint the surface with a carbolineum mixture consisting of 1 gal. of carbolineum and 1 gal. of water in which 1 lb. of whale-oil soap has been dissolved, or peel off the bark over the diseased area without injuring the underlying wood and cover the wound with a grafting wax consisting of 6 oz. of alcohol, 1 lb. of resin, 2 oz. of tallow, and 1 oz. of spirits of turpentine.

A further test of the methods of controlling scaly bark, previously noted (E. S. R., 23, p. 446), showed that in the main the recommendations therein given still hold good, but certain modifications are suggested, the line of treatment depending upon the condition of the trees and of the grove as a whole. If the disease is of recent appearance in the locality and is confined to 2 or 3 trees in a grove, the infected trees should be cut back to the stump and treated as previously suggested. If the disease is of long standing in a grove in which the trees are still looking fairly well, a thorough pruning out and spraying with Bordeaux mixture will effectually check its growth. When the trees are badly diseased, showing much dead wood and weakened limbs covered with scaly bark spots and spongy bark, they must be headed back in December and January, cutting out all the foliage and small branches and leaving only the body and larger limbs; the entire surface should then be painted with the carbolineum solution.

An extended study of citrus scab or verrucosis has been made, the results of which will be published later. In the spraying experiments for controlling this scab it was found that trees sprayed with Bordeaux mixture in November and again the following March were entirely free from the disease. The use of a carbolineum emulsion even up to 25 per cent in strength was less effective than the Bordeaux mixture.
In studying silver scurf, sometimes called "thrip marks," the conclusion was reached that a species of fungus, probably a Coniothyecium, is one of the main factors in producing the disease.

The characteristics of the red rot disease of sugar cane as it exists in Florida and methods for its control are given. The use of only healthy seed canes, dipping the seed canes in a 5:5:50 Bordeaux mixture just before planting, fall planting of the canes in place of bedding them, the burning of all trash in the old bed and of all diseased canes, and the gradual introduction of immune seedling varieties are suggested as remedies for combating this disease.

Infectious diseases of plants, F. Tidswell (Rpt. Govt. Bur. Microbiol. N. S. Wales, 1909, pp. 51-72, figs. 21, map 1).—This report includes a list of fungus diseases met with during the year, arranged according to hosts and prepared by H. Johnston, discussions of potato blight and other potato diseases, and experimental researches on bunt of wheat, maize smut, and a disease of banana trees.

The potato diseases given for New South Wales are as follows: Late blight, leaf spot (Alternaria solani), dry rot (Fusarium solani), scab (Oospora scabies), a nematode (Tylenchus devastated), and brown fleck. Brown fleck is a disease which is characterized by the occurrence of rusty brown areas of various sizes and shapes in the flesh of cut tubers. These spots may be one to several in each tuber, either separate or confluent into a large area, involving almost the whole tuber, and consisting of dead tissues. No parasite has yet been found associated with it, and the cause of the disease is unknown.

The report on maize smut prepared by H. Johnston and that on bunt of wheat prepared by Darnell-Smith have been previously noted from other sources (E. S. R., 22, p. 745; 24, p. 347).

The report on diseases of banana plants prepared by the author and H. Johnston includes a description of a banana disease in which the leaves turn a golden yellow, followed eventually by the breaking off near the ground of all the stalks and suckers, and gives the results of a microbiological examination of the fluid and tissues from the diseased parts. The specimen examined, consisting of the stock of a well-grown tree, showed an external irregular patch of several square inches which was discolored and softer to the touch than the surrounding tissue. On pressure a fluid exuded through fissures. Transverse and longitudinal sections of the stock gave off a foul odor and showed sodden tissues and much free liquid which existed between the leaf sheaths as well as the actual tissue. Sections of individual leaves showed discolored areas of gray, green, and light and dark brown, while the core of the plant was soft and in parts diluent, its ordinary fibrous character being replaced by a paste-like substance.

The disease apparently proceeds from below upward. A microscopical examination of the fluid and of diseased tissues revealed the presence of the larvae of 2 flies (Neocerara sphingera and a Phorid), one species of mites (Derma-

Protection against plant diseases in Ireland (Dept. Agr. and Tech. Instr. Ireland Jour., 11 (1911), No. 3, pp. 457-461).—A brief history is given of the legislation on the regulation or prohibition of dangerous insect and fungus pests of economic plants, including a summary of the more important acts and orders and the methods of administering them.

Contribution to the study of the sooty molds, G. Arnaud (Ann. Ecole Nat. Agr. Montpellier, u. scr., 10 (1911), Nos. 3, pp. 211-254, figs. 9; 4, pp. 255-330,
figs. 20).—This is a more extended treatment of these fungi than the author's previous papers on this subject (E. S. R., 24, p. 742), and includes studies on the polymorphism of the various species, the systematic value of the biological conditions, and the taxonomic classification of the genera and species.

The author describes as new 2 genera, Plecoconturea and Fumagospora. 4 subgenera, viz, Pleomorfeae, Telichosporina, Morfeae, and Leptocapnodium, and 6 new species as follows: `Pleosphaeria ilicis on the leaves of Querus ilicis, Telichospora capnodioides on the dead bark of Populus alba, T. salicis on the branches of Salix cinerea, Limacinaia spongiosa on the branches of Nornium oleander, Plecoconturea castagna on the branches and foliage of Pyrus malus and Eriobotrya japonica, and Fumagospora capnodioides on the leaves and foliage of various plants.

South African cereal rusts, with observations on the problem of breeding rust-resistant wheats, I. B. P. EVANS (Jour. Agr. Sci., 4 (1911), No. 1, pp. 95—104, dgm. 1).—Observations extending over 4 years but confined chiefly to the wheat-growing districts of the Transvaal, inoculation experiments with Puccinia graminis, and experiments on breeding rust-resistant wheats, are reported.

The following grain rusts were listed for South Africa: P. graminis on wheat, barley, oats, rye, Dactylis glomerata, Lolium temulentum, and Festuca elatior; P. triticina on wheat; P. coronifera on oats; and P. dispersa on rye.

The black rust (P. graminis) is the most serious, usually being present on all summer cereals, and in the low country theuredospore stage is often found throughout the entire year. It is stated that this rust thrives best and does the most damage during hot and dry spells, when it becomes so abundant that the soil beneath the plants is colored a rusty brown withuredospores. The rust first appears on wheat, and then on barley, oats, and rye in succession. No recidival stage of this rust was found in South Africa, and all attempts to germinate the teleutospores have failed. The author distinguishes 3 forms of P. graminis on cereals in South Africa, as follows: (1) A form on rye which never appears until late in the season after the plants are headed, and has only been found on the stalk but never on the leaves; this rust infects barley but not wheat or oats, and all attempts to infect the rye leaves with it have failed. (2) A form on wheat which infects wheat and barley, but not rye or oats; in the field during winter months the barley remains free from this rust, while adjacent wheat is badly rusted, but later during the summer the barley becomes highly susceptible. (3) The form on oats which does not infect wheat or barley. In India rust is unknown on oats, but the author states that the Indian oats grown in South Africa are highly susceptible to both P. graminis and P. coronifera.

In the rust-resistant breeding experiments in which Bobs Rust Proof and White Egyptian were used as immune and Wol Koren and Holstrool as susceptible varieties, it was found that rust (P. graminis) from the hybrid is not only able to infect the immune parent but produces a severer infection on the susceptible parent than the rust from the parent itself. In other words, the pathogenic properties of the rust seem to have become distinctly increased after its sojourn in the hybrid plant and it produces a far more severe infection than rust from the susceptible parent. These hybrid plants, therefore, may play a very important part in the transmission of rust organisms from susceptible to immune varieties. The rust in the hybrid also developed a profusion of teleutospores, while on both parent wheats teleutospores were very sparingly produced, if at all.

118-122, figs. 2).—After a brief discussion of the method of infection by the loose smut of these 2 cereals, the authors describe the various recognized methods of seed treatment for combating loose smut, including a discussion of the necessary apparatus and methods of procedure for disinfecting both small and large quantities of grain by either the hot-water or hot-air treatment.

Field experiments with wheat diseases, 1910-11, J. T. Priddham (Jour. Dept. Agr. Victoria, 9 (1911), No. 4, pp. 250-256).—Attention is called to the general prevalence and serious damage done to wheat crops every year by "take-all" (E. S. R., 25, p. 44) and also to the occurrence of this or a very similar disease on oats and barley.

The treatment of seed grain with formalin is claimed to have improved the germinating power as well as to have destroyed all external fungus spores. Tables are given showing the prevalence of "take-all" and the results of seed treatment with formalin, copper sulphate, and copper sulphate plus a 2 per cent salt solution.

Investigations on potato disease (second report), G. H. Pethybridge (Dept. Agr. and Tech. Instr. Ireland Jour., 11 (1911), No. 3, pp. 417-449, pls. 10).—This is a report on work conducted during 1910 at the temporary station for the study of plant diseases at Clifden, Ireland (E. S. R., 22, p. 746). It includes further studies on the life histories and means of controlling the late blight of the potato (Phytophthora infestans), yellowing or yellow blight, stalk or sclerotium disease (Sclerotinia sclerotiorum), Botrytis disease, black stalk rot (Bacillus melanogenes), Spongospora scab, Rhizoctonia scab (Hyphochlum solani), and leaf-roll disease.

Experiments on the infection of potato plants by wind-blown ascospores of S. sclerotiorum showed that such infection was possible. The author holds that the attacking of the potato plants by this disease occurs chiefly from ailerally borne spores and not from the soil.

Potato plants were also found attacked by a Botrytis which, the author claims, is distinct from the Sclerotinia disease. Observations and cultures failed to show any genetic connection between the 2 fungi, and further, the sclerotia differ morphologically and physiologically. The sclerotia of the S. sclerotiorum fungus produce ascospores, while the Botrytis sclerotia produce only tufts of conidia.

In a further study of the black stalk rot (see below) which is said to be caused by B. melanogenes, the author claims to have proved that this organism also rots turnips, swedes, carrots, and parsnips, but not mangels.

The leaf-roll disease as it appears in Ireland is caused, so it is claimed, by Verticillium alboatrum, the mycelium of which was often found in the brown vascular tracts of the plants, and also in the roots. Plants grown from diseased tubers were affected with leaf-roll disease.

A bacterial disease of the potato plant in Ireland and the organism causing it, G. H. Pethybridge and P. A. Murphy (Proc. Roy. Irish Acad., 29 (1911), No. 1, Sect. B, pp. 1-37, pls. 3).—This is a detailed study of the disease known as black stalk rot and the organism causing it, a preliminary account of which has been previously noted from another source (E. S. R., 24, p. 552).

The author describes similar diseases, the characters of this disease, the isolation of the causative organism, and its morphological and cultural characteristics, discusses its pathogenicity toward other plants, and compares the causative organism with allied species. The disease is characterized by a discoloration and drying up of the foliage, browning of the principal fibrovascular bundles of the stem, decay of the underground portions of the stalk, and rotting of the tubers. The causative organism is called Bacillus melanogenes.
It is claimed that the use of diseased seed tubers is mainly responsible for the spread of the disease, which not only causes losses to the growing crop but much heavier ones during storage.

A bibliography is appended.

**Experiments on the spraying of potatoes in County Louth, A. W. Older-SHAW (Dept. Agr. and Tech. Instr. Ireland Jour., 11 (1911), No. 3, pp. 450–456).**—The results are given of experiments conducted during 1908 to 1910 on the efficacy of various Bordeaux mixtures in controlling the late blight of the potato.

Soda and lime Bordeaux mixture and Woburn Bordeaux paste were used in the experiments. The Woburn Bordeaux paste proved to be inferior to both the soda and the lime Bordeaux mixture.

**Experiments on the influence of fertilizers on the leaf-roll disease of the potato and on the yield of tubers, Österspen (Mitt. Deut. Landw. Gesell., 26 (1911), No. 18, pp. 222–224).**—In experiments with stable manure and commercial fertilizers the leaf-roll disease was found to be worse on the unfertilized plats. It was also very serious on plats which contained no potash, and to a less extent on the plats which contained no phosphoric acid, while on the plats fertilized with stable manure and with a complete fertilizer containing nitrate of soda, potash, and phosphoric acid the outbreak of the disease was checked. The yield was found to be increased materially on all the fertilized plats as compared to the check plats.

**Sooty mold of tobacco, E. INglese (Bol. Tec. Coltiv. Tabacchi [Scalfati], 10 (1911), No. 2, pp. 81–89).**—The author describes the characters of this mold (Fumago vagans), gives the conditions under which it is usually found on the tobacco and the damage done by it, and suggests remedies for combating it.

It is claimed that the overrunning of the green parts of the tobacco plants by this fungus diminishes the absorbing and transforming power of the plant, thereby seriously affecting its photosynthesis and producing serious nutrition disturbances. The use of nitrate of soda to increase the vigor of the plant and spraying with tobacco decoctions to kill the aphids are the remedies suggested.

**The value of spraying fruit trees (Queensland Agr. Jour., 26 (1911), No. 5, pp. 266, 207).**—Attention is called to a statement in the monthly report for March on the fruit industry in the Stanthorpe district by J. Henderson, inspector under the Diseases in Plants Act. of the very favorable results obtained in controlling the American blight on badly infected apple trees, by spraying the trees several times during the winter months with a solution of red oil, followed, after the foliage appeared, by a weak kerosene oil emulsion wash applied with a brush to the cankers on the trunks and limbs missed by the red oil spray. The trees were almost entirely freed from the disease with this treatment and the wounds caused by the blight have healed up, leaving the trees in a fine, healthy condition.

**Plum trees killed by Eutypella prunastri (Gard. Chron., 3. ser., 49 (1911), No. 1274, p. 329).**—Attention is called to the frequent killing of young plum trees by this fungus in Cambridgeshire. The fungus girdles the bark of the main stem, thus killing it. Older plum trees and apple trees are not killed by the disease.

**Spraying experiments with peaches, M. A. Blake and A. J. Farley (New Jersey Stas. Bul. 236, pp. 3–30, pls. 12).**—The results of observations and tests conducted at Vineland during the season of 1910 with soluble sulphur solutions are given, together with directions for the preparation and application of self-boiled lime-sulphur mixtures for the control of peach scab.

The mixtures used in these tests were commercial lime-sulphur (1:100, 1: 125, and 1: 175), home-boiled lime-sulphur (1:80, 1:100, and 1:125, specific gravity 7717°—No. 5—11—5

**DISEASES OF PLANTS.**
1.21), self-boiled lime-sulphur (8:8:50), atomic sulphur (9:35), Pyrox (1:20), and Sulfoicide (1:400). Detailed results are given of the effects on the foliage of the various mixtures used, the effect of 1 early application of diluted concentrated lime-sulphur upon peach scab, the effect of early and late applications of self-boiled lime-sulphur, the effect of an early spraying with a soluble lime-sulphur followed by a second application of a soluble or self-boiled lime-sulphur, the effect of an early application of self-boiled lime-sulphur followed by an application of a diluted lime-sulphur and a self-boiled lime-sulphur, the effect of spraying young trees, and the effect upon brown rot of spraying to control peach scab.

As a result of these experiments it is claimed that it is unsafe to apply commercial concentrated lime-sulphur mixtures to peach foliage unless more dilute than 1:125, and some brands even burn the foliage when applied at this strength. Commercial lime-sulphur mixtures when diluted 1:150 or 1:175 do not injure the peach foliage, but have little effect upon peach scab. The atomic sulphur (a finely divided sulphur containing arsenate of lead) gave promising results against peach scab. It is held that the key to the control of peach scab is having a finely divided sulphur well distributed upon the leaves and fruit during a certain period. The authors, therefore, recommend that for the control of peach scab and brown rot 3 applications of the self-boiled lime-sulphur mixture be made, the first application just before the calyx is shed, and the other 2 at intervals of about 3 weeks.

A gum-inducing Diplodia of peach and orange, H. S. Fawcett and O. F. Burger (Mycologia, 3 (1911), No. 3, pp. 151-153).—A preliminary report is made on the isolation of a species of Diplodia from both peach and orange trees in Florida and of successful inoculations with pure mycelial cultures of the fungus which produced a copious gumming on healthy individuals of these 2 hosts.

The fungus was isolated from the interior of gummy peach branches obtained in 5 different counties in Florida, and also from gummy orange branches and decaying orange fruits. Ten series of experiments, including direct and cross inoculations on both hosts and covering a period of 5 months, were made by introducing pure mycelial cultures into cuts in the bark of 2-year-old peach trees and 1 to 3 year-old orange trees grown in pots in the greenhouse. Every peach tree thus inoculated developed gumming in from 4 to 7 days, and in one instance a deadened area was produced on the bark from which in 16 days after inoculation the pycnidia of the Diplodia developed. When bits of mycelium were placed in contact with uninjured bark of tender and green twigs, gumming was induced. In most instances the inoculations on the orange trees produced gum flow, while the cross inoculations from peach to orange and from orange to peach were successful in every instance.

The same fungus was also isolated from the rotting fruits of orange and grape-fruit, and was shown by inoculation experiments to produce a softness and decay of oranges, lemons, and apples. Portions of the fungus placed on the stalk end of plucked lemons and oranges produced decay, and the fungus was subsequently isolated from the interior of these fruits.

The microscopic morphology of the fungus agrees quite well with that of D. natalensis, which causes a decay in lemons and other citrus fruits in the Transvaal (E. S. R., 24, p. 157).

Report of assistant plant physiologist, B. F. Floyd (Florida Sta. Rpt. 1916, pp. LXVI-LXXVIII, figs. 4).—The work during the year has been a continuation of previous investigations on the abnormal tissues of citrus trees affected with die-back, melanose, yellow spotting, and frenching (E. S. R., 23, p. 447).
Experiments with different fertilizers, especially nitrogenous, on the spotting of citrus leaves and the subsequent leaf fall showed that this spotting was probably due to nutrition disturbances initiated by the use of nitrate fertilizers, but could be counteracted by the addition of a phosphatic fertilizer.

Experiments on the use of copper sulphate as a treatment for die-back, in which 4 gr. of the copper salt in powdered form was inserted beneath the bark of diseased trees, showed that after a lapse of about 21 months no beneficial results in controlling the disease. All untreated trees and 35 out of 46 diseased treated trees showed some symptoms of die-back at the close of the treatment. However, all the trees, both treated and untreated, showed a decided improvement in their general appearance and the die-back symptoms on both sets were much fewer than at the beginning of the experiments.

New fungicides for combating the mildew, V. Vermorel and E. Danton (Prog. Agr. et Vit. (Ed. l'Est-Centre), 32 (1911), No. 22, pp. 679-687).—The authors give formulas, methods of preparation, and properties of several new copper sprays, including a modified soda-Bordeaux mixture (E. S. R., 25, p. 354), a copper sulphate-soap mixture, a colloidal copper sulphate-soap spray (see page 459), and their new silver nitrate spray (E. S. R., 24, p. 51). The qualities of various soaps which may be used in making copper-soap sprays are also discussed.

Note on the cellulose content of oak wood, which had been changed by Thelephora perditis, Helbig (Naturw. Zeitschr. Forst u. Landw., 3 (1911), No. 5, pp. 246-250).—Tests for cellulose were made with the so-called sound wood, of the grayish yellow wood in the neighborhood of the cavities, and of the white lining of the cavities in the wood. The “sound” wood showed 47.18 per cent of cellulose, the grayish yellow wood 66.37 per cent, and the white wood 68.66 per cent, on the basis of the air-dried substance.

These results show that only a partial change into cellulose of the tissues surrounding the cavities occurred, and that more cellulose is found in the immediate lining tissues of the cavities than elsewhere in the diseased wood.

Notes on some species of Gymnosporangium in Colorado, E. Bethel (Mycologia, 3 (1911), No. 3, pp. 156-160, pl. 1, fig. 1).—The author figures and describes a new species of Gymnosporangium (G. kernianum) which produces witches' brooms from 2 in. to 2 ft. in diameter on the Utah cedar (Juniperus utahensis).

From field observations, the distribution, and the apparent roestelial characteristics of Acicadium gracilens, the author believes that it is probably the acelial stage of G. speciosum.

The blister rust of white pine, P. Spaulding (U. S. Dept. Agr., Bur. Plant Indus. Bul, 206, pp. 88, pls. 2, figs. 5).—This bulletin gives an account of the European blister rust (Cronartium ribicola) of white and other five-needle pines and includes a historical account of the fungus, its distribution throughout the world, its economic importance, hosts, life cycle, nomenclature, description, field characteristics of the blight on Pinus strobus, the source of diseased stock found in America, the blister rust situation in America, methods of combating it, possible effects of new hosts and climate upon the virulence of fungus plant diseases in general, practical suggestions, present system of handling importations, and legislation against plant diseases.

The disease is claimed to be an exceedingly dangerous one and has caused immense damage to white pine in all European countries wherever it has obtained a good foothold. It has been found in Norway, Sweden, Finland, Russia, Siberia, Japan, Austria-Hungary, Italy, Switzerland, Germany, Denmark, France, Belgium, Holland, Scotland, and England, and has been introduced into Kansas, New York, Vermont, New Hampshire, Massachusetts, Connecticut, Penn.
sylva\text{\textperiodcentered}nia, Indiana, and Ohio, and may be present in Minnesota and Ontario. It is known to have been shipped to 230 different localities in North America, but at the present time all known diseased stock has been destroyed.

The greatest damage done by the disease is in nurseries, where entire beds and even the entire stock have been rendered unsaleable. The following methods of combating the disease are suggested: Import no five-leaf pine and Ribes stock, carefully inspect any imported Ribes stock during the first season and preferably during the second season also, keep five-leaf pines well separated from Ribes stock if either is imported—at least 500 ft. apart—remove and burn all diseased pine trees, inspect all pine stock from the last of April to June 10 and Ribes stock from July 1 until late in the fall, and inspect diseased lots of pines the second spring.

A very extensive bibliography of some 250 titles is appended.

The bladder rust of Scots pine, G. H. Pethybridge (Dept. Agr. and Tech. \textit{Instr. Ireland Jour.}, 11 (1911), No. 3, pp. 500-502, pls. 2).—The author discusses the gross characters of this fungus \textit{(Peridermium pini corticola)}, the extent and character of the damage done by it, and its probable alternative hosts.

It is stated that many 40-year-old Scots pine trees are being killed by this rust in Waterford County, Ireland. The alternate stages of the rust were claimed by Liro (E. S. R., 21, p. 321) to occur on certain species of the housewort \textit{(Pedicularis palustris} and \textit{P. scoptrum carolinum)}, and it is stated that the rust should now be known as \textit{Cronartium peridermium pini}.

A new species of \textit{Alternaria}, L. L. Harter (\textit{Mycologia}, 3 (1911), No. 3, pp. 154, 155).—Attention is called to a leaf spot disease of \textit{Forsythia suspensa}, an ornamental shrub growing on the grounds of the United States Department of Agriculture. Subcircular gray spots were developed irregularly over the leaf surface and were surrounded by dead leaf tissue.

The causative organism is claimed to be a new species of \textit{Alternaria}, for which the name of \textit{A. forsythiae} is proposed. A technical description of the fungus is appended.

The fungicidal action of Bordeaux mixtures, R. T. P. Barker and C. T. Gimingham (\textit{Jour. Agr. Sci.}, 4 (1911), No. 1, pp. 76-94).—The authors discuss this under 3 heads, (1) the action of atmospheric agencies, (2) the action of the host plant, and (3) the action of the fungus, and they give the results of experiments on the action of the host and of the fungus on the spray.

It was found that when the epidermal cells of the host were entirely sound and unbroken, only an inappreciable amount of copper could be rendered soluble by the host. In regard to the action of the fungi in rendering soluble the copper present, it appeared that only very small quantities were thus made soluble throughout the entire Bordeaux mixture film on the leaf, but that when the spores or hyphae of several species of fungi were brought into direct contact with the insoluble particles of the copper compounds death ensued, probably due to a slight solvent action of the fungus on the particles.

The authors, therefore, claim that the fungicidal effect of Bordeaux mixture is not due to the absorption of atmospheric carbon dioxide by the spray, but is caused by the spores or hyphae of the fungus coming into direct contact with the insoluble particles of the copper compounds, thereby causing very minute quantities of the copper to become soluble, and thus causing the death of the adjacent spores.

The action of carbon dioxide on Bordeaux mixtures, C. T. Gimingham (\textit{Jour. Agr. Sci.}, 4 (1911), No. 1, pp. 69-75).—The results are given of experiments on the influence of carbon dioxide on the basic copper sulphates in rendering soluble the copper present in the mixtures.
The experiments consisted of blowing air for 20 and 45 minutes through a Bordeaux mixture containing pure copper sulphate, leaving the Bordeaux mixture exposed for 1 and 24 hours in open beakers with frequent stirring and shaking, and for the same time without any stirring, and of treating the Bordeaux mixture with carbon dioxid.

The conclusion reached in these experiments is that although an excess of carbon dioxid in the Bordeaux mixture renders soluble small quantities of the copper, yet it appears impossible to assign the fungicidal action of the Bordeaux mixture to copper sulphate liberated by atmospheric carbon dioxid alone.

A colloidal copper fungicide, V. Vermorel and E. Dantony (Compt. Rend. Acad. Sci. [Paris], 153 (1911), No. 19, pp. 1263-1265).—A description is given of a so-called colloidal copper-soap mixture. This is prepared by dissolving 500 gm. of copper sulphate in 50 liters of water and 2,000 gm. of soap, as rich as possible in oleate of soda and containing neither carbonate of soda nor alkaline hydrates in excess, in 50 liters of water, and then pouring the copper solution into the soap mixture. It is claimed that the resulting mixture will be an opaque blue-green liquid which wets the plants (grapes) as easily as alcohol and has marked fungicidal properties.

New lime-sulphur strainer, J. P. Stewart (Rural New Yorker, 70 (1911), No. 4088, p. 276, fig. 1).—The author figures and describes a strainer in which the liquid is strained upward instead of downward, thereby preventing the deposit of sediment on the screen, which is of common occurrence with the old types of strainers.

The strainer consists of a box with a vertical partition extending throughout the middle and down about half way, dividing the box into a shallow and a deep compartment. Across the bottom of the shallow portion is placed a 30 to 50 mesh screen of iron or brass. On pouring the spray material into the deep compartment it rises and passes through the strainer into the shallow compartment where it may be drawn off by a faucet as needed.

ENTOMOLOGY.

Under the heading of Insecticide Records, the author briefly considers tests with the arsenicals, sulphur solutions and compounds, vacuum oil, San-u-Zay scale oil, Cooper's V₅ fluid, Aspinwall's insecticide, and tobacco preparations.

The Chinese mantid is said to have definitely established itself in the State. Plant lice appeared in great numbers throughout the season. An outbreak of the army worm occurred at a number of points in 3 counties during the middle and latter half of June.

A report of investigations of root maggots in continuation of those previously noted (E. S. R., 22, p. 159) conducted by E. L. Dickerson is incorporated in the report (pp. 381-392). At Mercerville it was found on May 5 that oviposition had commenced on cabbage plants. In one patch “specimens of the red nite (Trombidium scribium) were noted—sometimes 2 about a single plant, in the work of destroying the eggs. In this patch several specimens of cynipid parasitc were also observed. In most cases they were moving actively upon the stems of the plants, but one was noted below the surface.” A strong solution of carbolic acid emulsion sprayed about the roots of cabbage plants on May 3, after the soil had been removed, did not injure the plants, but apparently killed all the maggots with which it came in contact.

The infestation of onions was found to be over by July 1, at which time all the flies had disappeared. Pegomyia vicina was observed June 7 working in beet
EXPERIMENT STATION RECORD.

leaves. The eggs, in clusters and from 1 to a dozen, were always placed on the underside of the leaves, in which the maggots burrowed between the upper and under surfaces. Carbolic acid emulsion made up of 10 qt. of acid, 10 lbs. of soap, and 10 gal. of water, much stronger than anything recommended, was used on May 18 at the rate of 1 gal. to 10 gal. of water after the soil had been removed from about the onions. The application killed the maggots wherever it came in contact with them and apparently did not injure the plants. Applications were made on May 8 and again on May 17 to rows of young onions on another place, but no difference was noted between the treated and check rows when examined June 12. “It appears that the carbolic acid emulsion is an effective killing agent when used at the proper strength. But it must be begun early and used frequently enough to reach the maggots.”

A carbolic acid fertilizer was applied in late April, just before the onion seed was sown, at the rate of 400 lbs. to the acre, and along other rows on May 8 and May 17, after the onions had sprouted, and again twice at weekly intervals. An examination made in early June showed that the material had not had any beneficial effect. An examination made in May of onions grown on soil treated with Apterite, applied broadcast on April 6 at the rate of 300 lbs. to the acre, showed no difference between treated and untreated areas, both being equally infested.

Examinations made June 7 of plats on which gas tar, 1 part to 25 parts of sand had been used, showed cauliflower and cabbage to be in fine condition, while on another farm where no application had been made considerable infestation was found.

It was found “that both *brassicae* and *fuscicaps* may pass the winter in the pupal stage and emerge during early May for a period of several days—perhaps half a month, or even longer; that both pupae covered deep, and those at the surface produced flies as well as those at a normal depth.” The rearings from 9 lots of maggots collected from cabbages, radishes, cauliflowers, and wild radishes are reported upon.

The other insects briefly considered are: San José scale, codling moth, *Vespa crabro* (which attacked ripe apples), pear psylla, plum curculio, peach borer, rose chafer, cranberry flea beetle (*Systena hudsonica*), elm-leaf beetle, gipsy and brown-tail moths, bronze birch borer (*Agrilus anxius*), and hickory-bark beetle.

Report of the superintendent of entomology for 1909-10, E. M. Ehrhorn ([Bion.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1909-10, pp. 103-151, pls. 7).—In the reports here submitted the details of inspection work are presented, together with lists of the insects intercepted, etc.

*Blastophaga grossorum*, which was introduced into Moanalua in May, 1909, appears to have become established. The work with parasites of the horn fly received from abroad during 1909 is reported by O. H. Swezey, and for 1910 by R. C. L. Perkins; the cryptid *Bathynectis* sp. was the only parasite that was bred successfully after arriving on the island. A brief account is given of fruit flies and a draft of the new rules and regulations for the prevention of the distribution of the Mediterranean fruit fly (*Ceratitis capitata*), which as previously noted (E. S. R., 24, p. 255) has been introduced into the island of Oahu. An additional rule and regulation concerning the importation of all banana fruit, banana shoots, and plants with a view to preventing the introduction of *Fusarium cubense*, which causes the banana blight, is included.

Correspondence with H. W. Henshaw, of the Biological Survey of this Department, in regard to the desirability of introducing foreign birds into the Hawaiian Islands for the purpose of destroying noxious insects is appended.
Report of the assistant entomologist, H. O. Marsh ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1909-10, pp. 152-159).—Experiments on the control of several insect enemies of truck crops, etc., including the Japanese beetle (Adoretus tenuimaculatus), the melon fly (Dacus cerurobitae), the alligator pear mealy bug (Pseudococcus nipe), the chrysanthemum plant louse (Macroscaphum sanborni), the beet worm (Hymenia fascialis), and insects affecting the cabbage are briefly reported.

Report on injurious insects in Finland, 1908, E. Reuter (Landlbr. Styr. Meddel. [Finland], 1910, No. 73, pp. 25).—The author discusses the occurrence of insect pests during the year. Charaxus granimis was the source of injury in the district of Österbotten, and the chrysomelid beetle Phaedra armoris is said to have injured turnips.

Some insect pests of India, H. E. Houghton and M. Adinarayanaiyai (Cent. Agr. Com. Madras Bul. 10, 1911, pp. 6, figs. 2).—The insect pests noted are the rice bug (Nayi puchi), rice hispa, 2 coconut beetles, tobacco caterpillar, and cane borers.

Research work—Parasites, P. Tidswell (Rpt. Govt. Bur. Microbiol. N. S. Wales, 1909, pp. 74-39).—The author presents a list of the parasites occurring in Australia, descriptions of certain parasites met with during the year, and brief notes on nematodes and nematodes. See also a previous note by Cleland and Johnston (E. S. R., 24, p. 785).

Synopsis, catalogue, and bibliography of North American Thysanoptera, with descriptions of new species, D. Moulton (U. S. Dept. Agr., Bur. Ent. Bul. 21, tech. scr., pp. 56, pls. 6).—This synopsis and catalogue lists a total of 118 species and varieties, representing 40 genera. Two genera, 10 species, and 1 variety are described as new to science.

Burning chinch bugs, T. J. Headlee (Kansas Sta. Circ. 16, pp. 7, figs. 6).—Attention is called to the fact that during the fall chinch bugs gather in large numbers in clump-forming grasses of badly infested sections and that most of them can be destroyed by running fire over the infested grass lands in such a way as to burn these clumps down close to the crowns.

Report of entomologist, E. W. Berger (Florida Sta. Rpt. 1910, pp. 335-346).—The greater part of this report is devoted to an account of sprayings made with red Aschersonia, a general discussion of which has been previously noted (E. S. R., 24, p. 353), and to the white fly situation in Florida in general.

It is stated that, as a whole, the fungus work with the white fly at Gainesville was a success. A sharp frost on December 30 and 31, 1909, defoliated many trees in a part of the experimental grove, resulting in a great loss of fungus but also causing a reduction of the white fly. Fungus collected on March 11, 1909, was kept in cold storage until August 8. Three lots exposed in various ways to temperatures of 12°, 26°, and 36° F., respectively, were sprayed August 11 on sterilized sweet potato, but only spores from the lot exposed to the temperature of 26° developed.

On trees sprayed August 17, 1909, with potash whale-oil soap No. 3, at the rate of 1 lb. to 9 gal. of water, 90 per cent of all larvae were destroyed. Similar results were obtained from the use of Golddust and whale-oil soap in a Satsuma grove. As previously observed, these spraying solutions did not retard the development of the fungus in the least. Whale-oil soap No. 3, 1 lb. to 6 gal. of water, also a mixture of whale-oil soap and baking soda at the rate of 1 lb. of the former to 13 lb. of the latter, in 8 gal. of water, destroyed nearly all larvae up to the thickened condition of the fourth stage. Spraying experiments showed that ½ lb. of washing soda to 1 gal. of water and ¼ lb. of borax to 1 gal. of water give no beneficial results. Black leaf tobacco extract at the rate of
1 part to 65 of water was found to be a far less effective agent against all stages than are soaps and other contact insecticides.

In August, 1909, specimens of Aleurodes numiferu were received from Lemon City, in Dade County, and later in the month it was found distributed in small numbers from north of Lemon City to Buena Vista and to the Bay Front. While the source of the infestation could not be determined, it was evident that the fly had been present longer than 2 years, and possibly 5 or 6, judging from its distribution. An examination made in September, 1909, to determine the number of adult white flies that are bred and liberated in a large China umbrella tree in Gainesville showed an average of 7.3 empty pupa cases per leaflet; 0.7 third-stage larvae; 12 fourth-stage larvae; and 4.2 pupae (an average for the 4 stages of 24.2); together with 1 dead larva.

The author concludes that when a freeze sufficient to nearly or completely defoliate trees occurs, the effects of such upon the white fly are about equivalent to a fumigation with hydrocyanic-acid gas.

Dipping peach trees to control peach root aphis, M. A. Blake and A. J. Farley (New Jersey Stat. Rpt. 1909, pp. 88-93, pls. 2).—Dipping experiments in which lime-sulphur made by boiling 15 lbs. of stone lime, 15 lbs. of sulphur, and 50 gal. of water for 1 hour; Scalecide 1 part to 16 of water; and whale-oil soap 1 lb. to 3 gal. of water, were used, are briefly reported.

"Three lots of 40 Elberta trees and 1 lot of 80 Elberta trees were selected for the experiment. One lot of 40 trees had their roots thoroughly dipped in the lime-sulphur solution, and another lot of 40 trees were dipped in Scalecide; 80 trees had their roots dipped in the whale-oil soap solution, and 40 trees were reserved without dipping for check trees. After the trees were dipped they were allowed to dry off slightly and were then 'heeled in.' . . . None of the trees failed to grow except 1 which was dipped in the whale-oil soap solution and it is very doubtful if the dipping was a factor in the death of the tree. All the trees made a very good growth during the season of 1908 and although in some instances it was possible to detect differences in growth between the various rows, these differences were not great enough on all the plats to permit of conclusive judgment by observation." In the late fall of 1908, after the leaves had fallen, measurements were taken of the annual growth made by each tree.

"The 40 trees dipped in lime-sulphur made a slightly better average growth than the undipped trees, but a comparison with the trees dipped in whale-oil soap solution seems to indicate that it is likely that the lime-sulphur checked the growth of the trees nearly as much as the aphis. The trees dipped in Scalecide made a somewhat better average growth than the lot dipped in lime-sulphur but some checking of growth is also apparently indicated. One average of 40 trees dipped in whale-oil soap solution shows an average increase of 90.3 in. of growth over the undipped trees, and the average of the other 40 trees dipped in whale-oil soap solution shows an average increase of over 200 in. of growth over the undipped trees. This indicates that the dipping was of considerable value."

Some experiments on the chrysanthemum plant louse (Macrocephum sanborni) H. O. Marsh ([Bien.] Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1909-10, pp. 169-172, pls. 3).—As a result of control experiments here reported, the author recommends the use of a mixture of Blackleaf 40 14 oz. and whale-oil soap 4 oz. to 5 gal. of water. The larvae and pupae of Leucopis nigricornis, the most abundant natural enemy of this plant louse, are not injured by this mixture.
The acidity of the sap of American vines in relation to their resistance to phylloxera, according to Comes, R. AVENA-SACCA (Abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intact, and Plant Diseases, 1910. No. 2, p. 336).—The author's investigations have led him to the following conclusions:

"Every circumstance which tends to decrease the natural acidity of the vines must tend to weaken their resistance to phylloxera. And since, in the South, the warm, dry condition of the plains, the superabundance of lime in the soil, and the careful cultivation (especially with farmyard manure) tend to diminish the acidity of the plants, it is clear that in sunny wine-growing regions of the South, in calcareous soils and in vineyards where there is intense cultivation, the original resistance of the American vines to phylloxera is enfeebled by degrees, and with time the vines reconstituted on American stocks deteriorate more or less seriously."

Papers on Coccidae or scale insects.—Catalogue of recently described Coccidae, III, E. R. SASSER (U. S. Dept. Agr., Bur. Ent. Bull. 16, pt. 4, tech. ser., pp. 61-74).—This part, which is in continuation of the catalogue by J. G. Sanders previously noted (E. S. R., 22, p. 551), is thought to be fairly complete up to March, 1911. It refers to 3 new subgenera, 98 new species, and 5 new varieties of scale insects.

Damage to sugar cane in Louisiana by the sugar-cane borer, T. C. BARBER (U. S. Dept. Agr., Bur. Ent. Circ. 139, pp. 12).—This borer has been the most serious enemy of sugar cane with which the Louisiana planter has had to contend for many years. During the course of observations and experiments conducted by the author in 1910, it was found to be responsible for much injury that is not apparent at first sight.

"Its harmful work begins with the destruction of eyes of seed cane, reducing the stand during the following year; continues through the growing season of the cane by stunting its growth, and causing damage from windstorms, owing to the weakening of the stalk due to the burrows and girdles; and ends by causing a much lower percentage of juice, which is again of a much poorer quality in infested canes than in uninfested canes. The last is an important form of injury, which appears to have been overlooked by investigators and planters. Moreover, the holes made by the cane borers are the chief means of entrance to the stalk afforded the various fungus diseases of the sugar cane. The tonnage yield per acre is reduced by borers, and the average weight of canes otherwise similar in appearance is found to be reduced by borer infestation."

The subject is taken up under the headings of injury to seed cane, injury to growing cane, and injury to mature cane and juice. Counts made of 3,834 canes showed 1,313 to be borer-free and 2,521, or 65.75 per cent, infested by the borer. Investigations conducted indicate that the difference in yield between borer-free and borer-infested cane fields amounts to about 1 ton of cane per acre when the borer-free cane gives a yield of 25 tons per acre, and that there is a loss of 1.075 lbs. of sucrose per acre.

Investigations of methods of control are now under way.

The root borer of the sugar cane (Agr. News [Barbados], 10 (1911), No. 240, p. 218, figs. 2).—The sugar cane root borer (Diaprepes abbreviatus), which appeared as a serious pest in a limited area in Barbados at the end of 1909 and early in 1910, was again in evidence and caused serious injury to ripening sugar cane during the early months of 1911.

Biology of the cochylis and eudemis moths, P. MARCIAL (Rev. Vit., 35 (1911), Nos. 903, pp. 381-385; 904, pp. 419-423).—The author presents a brief account of the biology of Cochylis ambiguella and Eudemis botrana, 2 of the
more important insect enemies of the grape in France and other European countries.

Combating the wood-boring caterpillars of Zeuzera pyrina in cork-oak forests, P. Lesne (Compt. Rend. Acad. Sci. [Paris], 152 (1911), No. 19, pp. 1269-1271).—In continuing work with this pest (E. S. R., 20, p. 354) the author in applying carbon bisulphid has made use of long slender gelatine capsules that can be readily introduced into the galleries. Experience has shown that 24 hours is a sufficient period of time for the capsule to be dissolved by the moisture present in the galleries and the larvae destroyed.

The injury to sugar beets by the Wintersaateule (Agrotis sp.) and methods of combating it, Wassiliew (Bl, Zuckerribenbau, 17 (1910), No. 20, pp. 330-332; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 1910, No. 2, p. 379).—Agrotis larvae are said to be the source of considerable injury to sugar beets in the Government of Kiev, Russia; they first consume the leaves and later the other parts of the plant.

Report of mosquito work for 1909, J. B. Smith (New Jersey Stas. Rpt. 1909, pp. 421-459, figs. 3).—During the year 360,800 ft. of ditching were dug and 2,672 acres drained, making a total of 3,464,974 ft. of ditching dug and 25,192 acres drained to date.

Brief mention is made of bats as enemies of mosquitoes and of an investigation made of the water plant (Azolla sp.), previously noted (E. S. R., 24, p. 562). Experiments conducted with iron sulphate and Culcis pipiens larvae show that at the rate of 1 oz. to 1 gal. of water this material is a good, and at double that rate, an effective destroyer of mosquito larvae and pupae. Under some circumstances it may be useful on a limited scale, but it will do nothing that petroleum will not do at much less expense.

The author finds that a concentrated extract like Nicofume is an exceedingly violent larvacide, and at the rate of 1 part to 2,500 of water will kill all larvae of C. pipiens. In experiments with Hyco it was found that at a dilution of 1 to 30,000 it can be relied upon to kill all larvae, except, perhaps, those just ready to pupate, but that 1 to 10,000 is the extreme limit of dilution effective against pupae and that, even here, adults would probably emerge safely from pupae just ready to transform. Under natural conditions no lasting results follow on the treated area, and within a day or 2 after the application the water is again safe for mosquito development.

A systematic fumigation of cellars in Newark and vicinity where mosquitoes hibernate in immense numbers, thousands in a single cellar in some instances, was discontinued after a few days, as the results were not as satisfactory as was expected. A chemical analysis of the stramonium used showed that the alkaloidal content of the drug varies greatly. When the material is stored, unless it is kept in very tight receptacles, it loses in strength and may in time become almost inert. The alkaloidal content of 6 samples of stramonium from as many different sources was found to be 0.32, 0.24, 0.15, 0.24, 0.02, and 0.12 per cent. respectively. The first, second, and fourth mentioned represent fresh, full-strength material; the third, fifth, and sixth represent the run of the market, ranging from fair to almost inert, the fifth being of little more value than so much dried hay.

The details of inspections made along the shore and in the vicinity of various cities follow. Notes of the Season, by J. A. Grossbeck (pp. 457-459), are appended to the report. The author finds that where natural breeding places are scarce, it is quite possible to attract C. pipiens for a considerable distance around to an artificial area where they can be kept under observation and control. "It seems indicated, also, that when such an attractive place is provided, the insects do not so readily bite or frequent even near-by dwellings.
This sort of trapping is quite feasible around any house with a garden, but it means also that the tub or pail must not be forgotten long enough to allow any brood to come to maturity. The larve can be killed off every few days with tobacco extract without affecting the water as to attractiveness for oviposition. . . . *C. salinarius* larve were found on Gilmore's Island on the Barnegat bay shore as late as December 1, 1908, not yet full grown."

Brief notes are also presented on *C. aurifer*, *C. rustans*, and *Anopheles punctipennis*.

Cerebral localization of a larval *C. Estrus*, D. Blasti (*Rev. Med. Vet. Montevideo*, 1 (1910), No. 11, pp. 430, 431; abs. in Vet. Rec., 23 (1911), No. 1187, p. 652).—The author reports the case of a sheep, 1 ½ years of age, in the right lateral ventricle of the brain of which a larva of *C. Estrus ovis* was found.

Introduction into Italy of an Indian hymenopteron to destroy the orange fly, F. Silvestri (*Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici*, 4 (1910), pp. 228-245, figs. 8; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intell. and Plant Diseases, 1910, No. 2, p. 375).—Syntomosphrynum indicum n. sp., a parasite of *Ceratitis capitata*, which was introduced from India into Italy in 1900 has been bred in large numbers, about 10,000 being distributed at Rosarno, Calabria.

Experiments with *Drosophila* ampelophila concerning evolution, F. E. Lutz (*Carnegie Inst. Washington Pub. 143*, 1911, pp. 40, figs. 53).—The greater part of this work deals with the inheritance of abnormal venation (pp. 1-35). The effect of sexual selection and disuse and degeneration are also briefly considered.

In regard to breeding habits the author states that this red-eyed pomace fly "is very common about cider mills, ripe fruit, vinegar barrels, and the like. The larve normally live in the pulp of rotting fruits, especially during the acetic acid stage of decay. They will, however, thrive on the side of a tumbler containing fruit juices, and I have reared them through several generations on stale beer. At a temperature of 25° C. the eggs hatch in 40 hours or less. The duration of the larval period is, on the average, 5 days and of the pupal period 4½ days. The adults become sexually mature about 48 hours after emergence when kept at this temperature. They live for about 3 weeks. The mean number of eggs is close to 200. Copulation is repeated and frequent."

The life history and control of the cacao beetle (Steirastoma depressum), P. L. Guppy (*Bd. Agr. Trindad Circ. 1*, 1911, pp. 33+III, pls. 4, figs. 4).—This is a detailed report of an investigation of the biology and of remedial measures for the cacao beetle.

An annotated bibliography of the Mexican cotton boll weevil, F. C. Bishop (*U. S. Dept. Agr., Bur. Ent. Circ.* 140, pp. 30).—This annotated bibliography of 237 titles is intended to serve as an index to the extensive literature on the Mexican cotton boll weevil.
FOODS—HUMAN NUTRITION.

Treatise on biochemistry, E. Lambling (Précets de Biochimie. Paris, 1911, pp. 600-622).—In this general treatise such questions are considered as the laws of energy in the animal body, protein and other nutrients, diastases, digestion and absorption of food, micro-organisms and their rôle in digestion, fermentation and intestinal putrefaction, and various problems of metabolism.

A treatise on foods and their effects upon health and the physical and moral life, S. P. Snyder (Dayton, Ohio, 1910, 2, cd., rev. and ed., pp. IX+183, pl. 1).—The author has collected a large number of recipes, the bulk of them for the preparation of simple dishes, and has discussed the effects of foods with relation to health, and other matters. In these discussions he makes little or no reference to the numerous scientific investigations of nutrition topics which have been published by many investigators, while theories such as are commonly advanced by different food cults are given great prominence. The general deductions are not such as are commonly advocated by students of physiology and nutrition.

Food adulteration. Its detection and control, A. Beythien (Samml. Chem. u. Chem. Tech. Vorträge. 16 (1910), No. 1, 3, pp. 140).—A valuable digest of data.

[Food control], D. A. De Jong et al. (Trans. IX. Internat. Vet. Cong. The Hague. I (1909), pp. 246, figs. 3, dyn. 1).—Food control, tropical diseases, and questions of animal production and veterinary medicine are considered with reference to hygiene.

Compilation of analyses of East Indian food materials, J. E. Q. Bosz (Bul. Kolon. Mus. Haarlem, 1911, No. 46, pp. 261, chart 1).—A vast number of analyses of food materials, including tropical fruits and other local products, are given in this extended compilation of data.

A colored chart which summarizes data graphically is appended.

The retail butcher, R. S. Matthews (Memphis. Tech., 1911, pp. 101, pl. 1, fig. 2, charts 4).—The proportion of the different cuts which a carcass yields, the sum at which different cuts should be sold in order to give a definite profit, methods of curing meat, and other questions are discussed with special reference to retail trade conditions.

Modern practice of canning meats, G. T. Hamel (St. Louis, 1911, pp. 100, figs. 19, dyn. 1).—Theories of canning are discussed. Equipment described, and recipes and formulas given in this handbook, which considers the subject from the standpoint of the small plant as well as from that of the large establishment.

The use of horse intestines as sausage cases, M. Müller (Ztschr. Fleisch u. Milchhyg., 21 (1910), No. 1, pp. 3-10).—From experimental studies by the biological method the author concludes that the use of horse intestines as casing for sausage made without the addition of horseflesh may, give results which will lead to erroneous conclusions regarding the character of the sausage.

The influence of meat extractives upon the resorption of nutritive materials—the physiological nutritive value of meat extract. W. Völitz and A. Baudrexl (Pflüger's Arch. Physiol., 138 (1911), No. 4-6, pp. 273-291).—In experiments with dogs the conclusion is drawn that adding meat extract to a basal ration which did not contain organic flavoring bodies did not increase the resorption of either nitrogenous or nitrogen-free nutrients. Under favorable conditions the protein-free extractives of meat assist in nitrogen retention in that the nitrogen loss on an insufficient diet is diminished by a value equivalent to at least 11 per cent of the nitrogen administered in the form of extractives. The
physiological nutritive value of meat extractives is, in round numbers, twotHIRDS OF their energy value.

Preparation of salmon caviar, L. Maynard (Daily Cons. and Trade Rpts. [U. S.], 15 (1911), No. 169, pp. 615-617).—The manufacture and use of salmon caviar, market conditions, and other similar topics are considered.

The introduction of milk into the army diet in Austria, A. R. Eielbeck (Milch Ztg., 39 (1910), No. 47, pp. 553, 554).—Some information is summarized regarding attempts made to use larger quantities of milk in soldiers’ rations, on account of its reasonable cost in proportion to the nutritive material it supplies.

The specific gravity of bread in relation to its water content, A. J. J. Vandeveld B. and A. Revijn (Separate from Verslag, en Meded. K. Vlaam. Acad. Taal en Letterk., 1910, pp. 8).—The study reported constitutes the seventh report from the School of Nutrition of the City Laboratory of Ghent.

From determinations of the weight, volume, specific gravity, and water content of bread baked in different ways some general conclusions were drawn. The specific gravity of the loaf appears to be more dependent upon the quality of the flour than upon the weight or form of the loaf or the method of baking. It is higher in small than in large loaves, though exceptions occur. The water content of the bread diminishes regularly during baking. The form of the loaf apparently exercises no effect upon this factor.

Bread—its value in the ration, G. H. Estes (Infantry Jour., 7 (1911), No. 5, pp. 716-726).—The composition and use of bread, bread making, and other similar questions are considered with special reference to army conditions.

[Supplying bread to farm employees], J. Renard (Jour. Agr. Prat., n. ser., 20 (1910), No. 50, p. 753).—A project is described by which bread is made and sold at low cost to employees.

Concerning bananas, K. Yoshimura (Ztschr. Untersuch. Nahr. u. Genussmll., 21 (1910), No. 7, pp. 406-411).—Studies are reported of bananas at different stages during the ripening period, from which the author concludes that the tannin content of the banana remains unchanged during ripening. Starch is changed into saccharose, which later is in part or wholly inverted by means of invertase, there being no constant relation between the saccharose and invert sugar. No sugars except these two were found in bananas.

Vinegar, A. McGill (Lab. Inland Rcv. Dept. Canada Bul. 223, pp. 19).—Data are given regarding the examination of 84 samples of vinegar, and vinegar standards are proposed.

A new coffee adulterant, C. Greibel and E. Bergmann (Ztschr. Untersuch. Nahr. u. Genussmll., 21 (1911), No. 8, pp. 481-484, figs. 3).—According to the authors, the principal materials found as coffee adulterants in Berlin are the seed of blue lupines (Lupinus angustifolius), and more recently the seed of common vetch (Lathyrus sativus). The seed of this vetch, when used for a long time, may induce chronic poisoning. With a view to detecting the presence of vetch seeds, their appearance and histological structure are described and a proximate analysis reported of the raw seed.

Food inspection decision (U. S. Dept. Agr., Food Insp. Decision 136, pp. 2).—This decision has to do with the labeling of chocolate and cocoa.

After considering evidence submitted, the board of food and drug inspection reached the conclusion that the definitions laid down in a previous publication (E. S. R., 18, p. 459) are substantially correct.

Food inspection decision (U. S. Dept. Agr., Food Insp. Decision 137, p. 1).—This decision has to do with the use of charlock as a substitute for mustard.

In the opinion of the board of food and drug inspection, when such a substitution is made the label clearly state the fact.
Notices of judgment (U. S. Dept. Agr., Notices of Judgment 846, pp. 8; 848-849, pp. 2 each; 850, pp. 16; 851, pp. 2; 852, p. 1; 853-858, pp. 2 each; 859, p. 1; 860-866, pp. 2 each; 869-870, p. 1 each; 871-872, pp. 2 each; 873, pp. 4; 874, pp. 3; 875-876, pp. 2 each; 877, pp. 3; 878-880, p. 1 each; 881-882, pp. 2 each; 883, p. 1; 884-885, pp. 2 each; 886-890, p. 1 each; 891-892, pp. 2 each; 893, p. 1; 894, pp. 2).—These notices of judgment have to do with the misbranding of molasses, macaroni, Mohawk brand Neufchatel cream cheese, drug products, sorghum sirup, "Uncle Sam antisyptic breakfast food," bottled beer, cheese, compound fruit jelly, asthma cure and blood cures, and sirup; the adulteration of Macalren's imperial cheese, desiccated eggs, crystal eggs, olives, frozen eggs, turpentine, tomato pulp, corn meal, tomato catsup, frozen egg product, and tomato paste; the adulteration and misbranding of vinegar, apricot brandy and blackberry cordial, orange flavor, a food product, orange extract, canned tomatoes, Ozone vichy water, drug products, powdered cloves, vanilla extract, and strawberry fruit flavor and raspberry fruit sirup; the misbranding and alleged adulteration of turpentine; and the alleged adulteration of a drug product.

Eight: biennial report of the dairy and food commissioner for the biennial period ending October 31, 1910, L. Davies (Brev. Rpt. Dairy and Food Comr. Wash., 8 (1909-10), pp. 35).—Of the 1,164 samples of extracts, honey, spices, baking powder, condensed milk, breakfast food, ice-cream cones, and other materials examined, 831 were found to comply with the law, while 333 were illegal. The work of the department, including dairy inspection, is discussed at length.

[Diet of South American natives], P. Walle (In Au Pays de l'Or Noir. Paris [1909], pp. 26, 27).—Fish, meat, cassava flour, and Indian corn are mentioned as staple foods in this brief account of food habits and dietary customs of South American natives.

Cost of living in American towns, H. L. Smith (London: Govt., 1911, pp. XCI+533, map 1; U. S. Senate, 62. Cong., 1. Sess., Doc. 22, pp. XCI+533).—Continuing work previously noted (E. S. R., 23, p. 169), extended studies were made in 28 American towns on or east of the Mississippi River, their aggregate population in 1910 being 15,488,140.

The range of price levels for rents was found to vary greatly, being highest in New York City. The prices of the principal foodstuffs, such as bread, flour, meat, potatoes, and sugar, did not show great range in the different towns, as was evident from the fact that when each article is considered in its relative importance the lowest level is 91 and the highest 100, with New York midway counting as 100. "If the towns are grouped geographically the New England and southern groups show the highest food price levels, the Middle West towns the lowest, the position of the New England towns in regard both to wages and rents being here reversed."

As regards retail prices of foods, the conclusion is that the ratio between the United States and England and Wales is 138 to 100.

"One peculiarity shown by the budgets is the comparatively small consumption of baker's bread in the average American working-class family, the consumption being 8½ lbs. weekly per family as against 22 lbs. in the United Kingdom, the place of bread being taken in the United States to some extent by rolls, cakes, biscuits, etc., on which the expenditure is about three times as great as that shown in the average British budget. On the other hand, the consumption of meat is much larger in the United States, and the consumption of vegetables is also larger. The budgets indicate in general that the dietary of American working-class families is more liberal and more varied than that of corresponding families in the United Kingdom."
For purposes of comparison it is calculated that if an English workman with an average family were maintained under American conditions in the same standard as regards food consumption to which he has been accustomed his wages "would be higher in the United States by about 130 per cent, with slightly shorter hours, while on the other hand his expenditure on food and rent would be higher by about 52 per cent."

In addition to general discussions the report contains the details of the family budgets and other statistical data collected.

**Cost of living in Switzerland,** D. L. Murphy (Daily Cons. and Trade Rpts. [U. S.], 14 (1911), No. 118, pp. 792, 793).—In connection with this summary of statistical data some information is given regarding an attempt made in St. Gall to lower prices by eliminating middlemen.

**Report of an investigation of the methods of fiscal control of state institutions,** H. C. Wright (State Charities Aid Assoc. [N. Y.] Pub. 122, 1911, pp. 353).—Two papers are included in this report, namely, a study of methods of fiscal control in state institutions in New York, and a comparison of the methods of fiscal control in state institutions in New York, Indiana, and Iowa.

From an extended study of the kind and character of foods and other supplies and the situation as a whole in state institutions in New York, the author concludes that the joint contract system followed in the purchase of supplies is subject to many criticisms and that such centralization is not necessarily economical. The detailed criticisms are of especial interest to those concerned with questions of institution management, as is also the critical comparison of the methods of purchasing supplies in New York, Iowa, and Indiana, reported in the second paper.

According to the author's conclusions, "an institution with an inmate population of 400 or over can ordinarily secure at low prices as can a central body with power to contract for large quantities. . . .

"In those institutions which seem to do the best work and seem to care for the inmates most satisfactorily, the superintendent is given, under the general direction of the board of managers, a large degree of liberty with a corresponding responsibility."

From the data which he secured the author has calculated the food supplied annually per capita and its cost, and the protein and energy content of the food supplied per man per day in 13 institutions in New York, 9 in Indiana, and 7 in Iowa, including hospitals for the insane, soldiers' homes, industrial schools, reformatories, prisons, and institutions for the feeble-minded and for epileptics.

Average data are summarized in the following table:

**Average food per man per year and nutritive value of daily ration in public institutions.**

<table>

The diet in different institutions is discussed at length and much interesting material is recorded.

The report contains an introduction by H. Folks.

Housekeeping efficiency, C. Barnard (Housekeeping Expt. Sta. [Conn.] Bul. 11, pp. 20, pls. 3).—Increased efficiency through correct house planning, the use of conveniences and labor-saving devices, and the elimination of needless work are discussed, and data recorded regarding the actual labor involved in performing a definite task by different methods.

[Problems of infant feeding] (Amer. Assoc. Study and Prev. Infant Mortality Trans., 1 (1910), pp. 356, pls. 11, dgm. 38).—Papers which have to do with problems of infant feeding, milk supply, questions of home management, education, and similar subjects are included in this report of the annual meeting held in Baltimore, Md., November 9-11, 1910.

The time food remains in the body, and intestinal activity as affected by treatment by warm flushing, A. Hiller (Deut. Med. Wochenschr., 37 (1911), No. 17, pp. 781-784, dgm. 1).—According to the author's conclusions, any given meal does not pass through the intestine as a continuous mass, but various portions may be widely separated during digestion. The influence of intestinal movements on the passage of food through the digestive tract is discussed. It was found that with healthy individuals food remained in the intestine from 18 to 42 hours. Raw peas were used as markers. Data obtained under pathological conditions are also discussed.

The tryptic digestion of casein, M. Siegfried (Pflüger's Arch. Physiol., 136 (1910), pp. 165-202).—The results of an extended study are reported. According to the author, trypsin-casein-peptone on hydrolysis yields the largest amount of ammonia and the smallest amount of nitrogenous material precipitated by phosphotungstic acid of any of the materials studied by the method used.

The influence of caffein on protein metabolism in dogs, with some remarks on demethylation in the body, W. Salant and I. K. Phelps (Jour. Pharmacol. and Expt. Ther., 2 (1911), No. 4, pp. 401, 402).—The results of experiments were reported in a paper presented at the second annual meeting of the American Society for Pharmacology and Experimental Therapeutics.

"The resistance to caffein was found to vary with the amounts of the urinary purins eliminated."

The elimination of creatin and creatinin after the administration of caffein, W. Salant and J. R. Rieger (Jour. Pharmacol. and Expt. Ther., 2 (1911), No. 4, pp. 400, 401).—A brief abstract of a paper presented at the second annual meeting of the American Society for Pharmacology and Experimental Therapeutics.

According to the authors, experiments on rabbits indicate that urinary creatin is increased after the administration of caffein, the size of the dose being an important factor. Neither the increased diuresis nor the diminished appetite observed could, in the authors' opinion, be regarded as a factor in accounting for the increased output of creatin. "The elimination of the creatinin was variable in some rabbits, but in most of them it was practically not affected by caffein."

Chemical and microscopical studies of the transportation of fat through the intestinal wall in resorption, A. Noll (Pflüger's Arch. Physiol., 136 (1910), pp. 208-247).—In general, the author concludes, on the basis of his
experimental evidence, that the phenomena of fat transportation which can be detected with the microscope represent only a part of the entire process.

A strength and endurance test, C. F. Langworthy (Science, n. ser., 33 (1911), No. 853, pp. 708-711).—In a contest entered into for a wager 48 men endeavored to carry on the back a weight of 100 lbs. for approximately 10 miles. Of this number 6 completed the task, while the others dropped out at various stages. The information collected from a number of the men showed that they lived on a simple mixed diet. The energy expended in moving the body and carrying the load over the course was calculated to be 1,137 calories on an average for the 6 successful contestants, of which amount 707 calories would represent the energy expenditure for motion of forward progression and 430 calories the energy expended in moving the load.

Similar calculations for individuals and for groups are reported.

It seems fair to conclude that the men who engaged in the contest were, as regards their food, their occupation, and their general living conditions, representative of a very large group of our population who are living comfortably and meeting their daily obligations in a creditable manner, who are, in fact, living the average life of the average man, with its varied activities and interests.

"In so far as the recorded data throw light on the subject, they indicate that the average man living the average life is capable of meeting body demands of considerable severity—a conclusion which perhaps few would question, but which it is interesting to consider in the light of numerical data."

Effects on men at rest of breathing oxygen-rich gas mixtures, F. G. Benedict and H. L. Higgins (Amer. Jour. Physiol., 28 (1911), No. 1, pp. 1-28, fig. 1).—From tests with normal individuals lying down at complete muscular rest 12 hours after the last meal and breathing air mixtures containing 40, 60, and 90 per cent oxygen, respectively, it was found "that there is no apparent difference between the metabolism as indicated by the gaseous exchange (i.e., the carbon dioxide output, oxygen consumption, and respiratory quotient) and the metabolism when breathing ordinary air; that there is no change in the respiration, either as to character, depth, or frequency, as compared with the same factors when breathing ordinary air; [and] that the pulse rate is lower with oxygen-rich mixtures than when breathing ordinary air; furthermore, that the higher the percentage of oxygen breathed (up to 90 per cent), the lower the pulse."

A respiration apparatus for the determination of the carbon dioxide produced by small animals, F. G. Benedict and J. Homans (Amer. Jour. Physiol., 28 (1911), No. 1, pp. 29-48, figs. 2).—A respiration apparatus of a size suitable for experiments with small animals has been constructed and is described. A kymograph is used in connection with it to indicate the muscular activity of the animal.

According to the authors, the closed-chamber method for determining carbon dioxide in short experiments with small animals is to be strongly recommended for a preliminary survey of many research problems in animal metabolism, though it is not offered as a substitute for direct determinations of oxygen and heat.

Handbook of physiological methods.—Nutrition, edited by R. Tigerstedt (Handbuch der Physiologischen Methoden. Ernährung. Leipsic, 1911, vol. 1, pt. 3, pp. 228, figs. 137).—Three papers are included in this handbook, namely: Metabolism, by W. Caspari and N. Zuntz; Respiration Apparatus, by R. Tigerstedt; and Calorimetry, by M. Rubner, each of which provides a historical and critical summary of work which has been accomplished.
ANIMAL PRODUCTION.

[Man and animals], edited by H. Kraemer (Der Mensch und die Erde, Berlin, Leipsic, and Stuttgart, 1906, vol. 1, pp. XII—500, pls. 34, figs. 173; 2, pp. XIII + 515, pls. 45, figs. 293).—The first two volumes of this series consist of articles of a popular nature, written by different authors, on domesticated animals and on the value of wild and domesticated animals to agriculture, commerce, science, and medicine.

The Vienna institution for experimental biology, C. L. Edwards (Pop. Sci. Mo., 78 (1911), No. 6, pp. 584—601, figs. 18).—An outline of the work undertaken at this institution is given, together with a description of the equipment employed in caring for the animals used in studying variation, inheritance of functional adaptations, and other problems in heredity and biology.

The relation of biology to agriculture, F. R. Marshall (Pop. Sci. Mo., 78 (1911), No. 6, pp. 539—553).—An appreciation of the value to agriculture of various phases of biological research.

It is pointed out that aside from the field of economic entomology the studies of botanists have contributed more to agriculture than those of zoologists, and that the expectations of the more sanguine Mendelians have not been realized because they overlooked the fact "that we are not able to originate any specific character desired; that not all characters are transmitted in accordance with the Mendelian formula: and that, except for purposes of research, it is seldom practicable to breed for but one single or unit character at a time."

The measurement of natural selection, J. A. Harris (Pop. Sci. Mo., 78 (1911), No. 6, pp. 521—538, figs. 7).—This is written to show that natural selection, like artificial selection and other factors which may affect a change in type of animals and plants, is capable of direct measurement. The work already done along this line is summarized.

Pure lines in the study of genetics in lower organisms, H. S. Jennings (Amer. Nat., 45 (1911), No. 530, pp. 79—89, dgm. 1).—Concrete examples are given to illustrate the meaning of genotype. It is pointed out that in work in genetics, as well as in other fields of biology, a mixture of "unknown genotypes will always give confused and ambiguous results, whose significance no one can know. If, on the other hand we work with single genotypes, or with known combinations of them, we shall understand what our results mean."

The biometric proof of the pure line theory, J. A. Harris (Amer. Nat., 45 (1911), No. 534, pp. 346—363).—This paper presents the pure line theory as it appears to the biometrician, and indicates methods of work which seem necessary to the drawing of sound conclusions.

It is stated that the work of Pearl, previously noted (E. S. R., 24, p. 675), and of others can not be cited in support of the pure line theory or that selection in general is without effect, on the following grounds: (1) Characters which are not inherited at all can not be taken to prove that selection in general is ineffective; (2) improvement of any single character can not be supposed to be unlimited; (3) selection can not in general carry a character beyond a degree consistent with the optimum for maintenance and reproduction.

Biometric arguments regarding the genotype concept, R. Pearl (Amer. Nat., 45 (1911), No. 537, pp. 561—566).—A reply to criticisms noted above.

The thymus and sexual organs.—III, Their relationship to the growth of the animal, D. N. Paton (Jour. Physiol., 42 (1911), No. 4, pp. 267–282, fig. 1).—The removal of the thymus retarded the growth of the testes in young guinea pigs, but not in those weighing above 300 gm. The simultaneous removal of the thymus and testes in very young guinea pigs checked the growth of the animals, but the removal of the testes or thymus alone had no effect upon the growth. Female guinea pigs deprived of the thymus at an early age became pregnant about the same time as normal animals. Ovariectomy and ovariotomy with thymus extraction appeared to exercise no effect on the rate of growth of the immature females.

These results indicate that in the guinea pig both the thymus and testes exercise an influence on the growth of immature animals, and that after the removal of one of these organs the other can compensate in part at least for the loss of the other.

On metallic coloring in birds and insects, A. A. Michelson (Phil. Mag. and Jour. Sci., 21 (1911), No. 124, pp. 554–567).—This is a study of the iridescent plumage of pigeons, peacocks, fowls, butterflies, and other animals caused by reflected light as distinguished from the colors due directly to pigments. In optical tests with polarized light measurements were made of the phase differences and amplitude ratios for various angles of incidence. The difficulty encountered by the absence of a true optical surface was met by replacing the objective collimator and of the observing telescope by low-power microscope objectives of small aperture.

The results indicate that the iridescence is due to an extremely thin film of some substances closely analogous in optical qualities to thin films of anilin dyes.

Experimental investigations on the inheritance of hyperdactylism of fowls.—III, Control experiments and experiments with common fowls, D. Barfurth (Arch. Entwickl. Mech. Organ., 31 (1911), No. 3, pp. 479–511).—Hyperdactylism in common fowls was found to be inherited independently of sex, as in the case of Orpingtons (E. S. R., 21, p. 572), and may remain latent over one generation. The author does not think hyperdactylism is inherited in Mendelian proportion.

Inheritance of fecundity in the domestic fowl, R. Pearl (Amer. Nat., 45 (1911), No. 534, pp. 321–345, figs. 5).—The purpose of this paper was to present figures sufficient to indicate with some degree of probability that egg production in fowls is inherited, and "probably inherited in accord with the genotype concept in spite of the fact that we do not and can not here have pure lines in the strict sense of Johannsen’s definition."

The winter egg production of each generation of represented pedigrees showing high and low fecundity lines are presented in graphic form. The aim since 1907 has been to discover and propagate genotypes of high and low fecundity, and the effectiveness of the selection is shown in the following mean winter production with high fecundity lines: 1908–9, 54.16; 1909–10, 47.57; 1910–11, 50.58, as compared with 22.06, 25.05, and 17, respectively, for all low fecundity lines. Effectiveness of selection within the genotype was found to be without influence.

The differentiation of sex and the relation of the sex in chicks, E. Thomas (Arch. Entwickl. Mech. Organ., 31 (1911), No. 3, pp. 512–539, pls. 2).—The sex of incubating chicks could be determined microscopically on the fifth day, and macroscopically on the ninth day. The secondary sexual characters were established before hatching. Of 805 chicks 385 were males.

A bibliography is appended.
The structure of the reproductive organs in the free-martin, with a theory of the significance of the abnormality, D. B. Hart (Proc. Roy. Soc. Edinb., 30 (1909–10), No. 3, pp. 230–241, pls. 2; Jour. Compar. Path. and Ther., 23 (1910), No. 3, pp. 193–206, figs. 5; also separate).—The sex organs of hermaphrodites and sterile cattle are illustrated and described. There is also a further discussion of the significance of the free-martin (E. S. R., 22, p. 472).

"The free-martin is, according to Mendelian phraseology, a pure or extracted recessive quâ its genital determinants, and the potent twin a pure or extracted dominant, both of \( F^2 \) in the Mendelian scheme. Occasionally, but very rarely, as in three of Numan's cases, the recessive element is less complete."

A bibliography is appended.

The influence of castration on organisms.—IV, The conformation of castrated heifers, J. Tandler and K. Keller (Arch. Entwickl. Meth. Organ., 31 (1910), No. 2, pp. 289–306, pl. 1, fig. 1).—Measurements of desexed heifers show that in conformation they approach the type of a castrated male rather than that of a normal male. In this respect the results agree with those of the authors' previous studies of human beings. It is stated that desexing both males and females causes them to resemble an intermediate or asexual type rather than to assume the characteristics of the opposite sex.

Report of the animal industrialist, J. M. Scott (Florida Sta. Rpt. 1910, pp. XIV–XVIII).—As in earlier work (E. S. R., 23, p. 78) velvet beans in the pod were found to be a cheaper protein dairy feed than cottonseed meal. When the basal ration was wheat bran and Japanese cane silage the cost of milk with the former ration was 13.3 cts. per gallon, and with the latter ration 16.5 cts. per gallon. It is estimated that when cotton-seed meal is worth $1.00 per hundred, velvet beans in the pod are worth $1.58 per hundred for dairy cows. Velvet beans in the pod also require 30 per cent less roughage than when cottonseed meal is fed.

In a pig-feeding test 5 pigs on a ration of corn, Japanese cane, and velvet beans in the pod made an average daily gain in 51 days of 0.71 lb. per head at a cost of 8.6 cts. per pound.

In a steer-feeding experiment Shorthorns made an average daily gain in weight for the first year of 1.07 lbs., Herefords 0.97 lb., and the natives 1.095 lbs. per head.

Wintering young store cattle, J. L. Duncan (Dept. Agr. and Tech. Instr. Ireland Jour., 11 (1910), No. 1, pp. 142–156).—Calves born in the autumn made faster gains during the winter when housed at night in a well-ventilated shed than did calves which received no shelter, but by midsummer there was little difference in the 2 lots. Wet weather had a more injurious effect on the unprotected cattle than did a protracted cold spell.

The practicability of supplying native beef to the army, G. E. Nesom (Philippine Agr. Rev. [English Ed.], 4 (1911), No. 3, pp. 119–121).—This contains statistics on the live stock in the different provinces of the Philippines, which total nearly 250,000 head of cattle and nearly 750,000 head of water buffaloes. There are also data on the number of cattle slaughtered and on the amount of meat used by the army in the Philippines. It is pointed out that the Philippines are extensive importers of both live stock and meat products, but that the islands can become a great grazing country in the future, if the contagious diseases now menacing the industry can be controlled.

The native cattle of Finland (Deut. Landw. Presse, 38 (1911), No. 31, pp. 370, 371, figs. 5).—This is a review of a monograph by H. Nylander, which contains a history of cattle breeding in Finland and a description of the native breeds of cattle.
The history of the development of the different breeds of cattle in Bavaria, Attinger (Deut. Landw. Tierzucht. 15 (1911), Nos. 19, pp. 221, 222; 20, pp. 233, 234).—A historical account of improved methods of breeding, and of the influence of introduced breeds of cattle.

Feeding sheep and lambs: Clover hay v. native hay; turnips v. dry ration, T. R. Arell (New Hampshire Sta. Bul. 152, pp. 3–19, figs. 6).—This reports the results of feeding tests conducted during 1909–10 to test the relative feeding values for sheep of (1) clover hay v. the ordinary hay mixture of very variable composition and designated native hay, grown in New Hampshire, and (2) turnips in conjunction with grain and hay v. a dry ration of grain and hay.

In the first experiment 4 lots of sheep were used, five in each lot, 2 lots consisting of ewe lambs of the mutton breeds, and the others of 2 to 3-year-old ewes, either Rambouillet or the ordinary grade stock of New Hampshire. Both lots of lambs were fed an equal quantity of a mixture of corn, bran, and oats (equal parts by weight) and turnips. In addition one lot was fed clover hay, the other an equal quantity of native hay. With the aged ewes the same plan was followed with the hay, but they were fed only turnips besides. Analyses of all the feeds and digestion coefficients of the native hay are reported.

The lambs fed clover hay made an average daily gain of 0.35 lb. per lamb at a cost of 7.66 cts. per pound; those fed native hay, 0.229 lb. at a cost of 12.4 cts. The corresponding figures for the aged ewes were 0.184 lb. at a cost of 16.24 cts., and 0.065 lb. at a cost of 42.87 cts., respectively. The poor results with native hay were due to the fact that it contained large quantities of timothy and other grasses that the sheep did not relish. Farmers are advised to sell their timothy and native hay and purchase for their sheep clover or alfalfa hay.

In the second test 10 ewe lambs of the mutton breeds were divided into two lots. Lot 1 was fed grain (oats, bran, and corn in equal parts by weight) and clover hay; lot 2, the grain mixture, clover hay, and turnips. The amount of grain and clover hay given to lot 2 was so reduced that the cost of the ration would equal that of lot 1. Lot 1 made an average daily gain per lamb of 0.29 lb. at a cost of 11.96 cts. per pound; lot 2 a daily gain of 0.378 lb. at a cost of 9.60 cts. The results of this experiment were very striking. In every instance the turnip-fed lambs made decidedly better gains than those fed the dry ration. This was especially apparent toward the end of the test. The difference is attributed to a stagnation of the appetite of those fed the dry ration. “The turnip-fed lambs eagerly sought and would have eaten more.”

The pig, F. Faelli (Il Porco. Milan, 1911, pp. 461; rev. in Vet. Jour., 67 (1911), No. 531, pp. 311, 312).—A pioneer work on the breeds, breeding, feeding, and management of swine from the Italian point of view.

Is German meat meal a good feed for swine? M. Popp, W. Felling and F. Schütze (Deut. Landw. Presse, 38 (1911), Nos. 37, pp. 429, 430; 38, pp. 440, 441, figs. 4).—Meat meal proved to have about the same value as fish meal when used as a supplement to barley and in mixed rations for swine. It was superior to a proprietary mixed feed or to a ration composed entirely of barley. Analyses of feeds and results of slaughter tests are given.

The conditions underlying the breeding of Percherons, and a comparison of their form with the Boulonnais and Belgian breeds based on official measurements, W. Gotzmann (Landw. Jahrb., 30 (1911), No. 1–2, pp. 1–81, pls. 3).—This treats of the origin, characteristics, and geographic distribution of the Percherons. Measurements of 515 Percherons are presented in tabular form.
The single testing system of breeding for egg production, D. F. Laurie (Jour. Dept. Agr. So. Aust., 11 (1911), No. 8, pp. 748-759, figs. 3).—In order to detect good layers from which to breed, the author advocates the keeping of hens in single pens instead of using trap nests. Details are given for the management of the hens and the keeping of records when this system is used.

The Buckeye; one of the newer breeds, Mrs. Gertrude O. Earl and A. H. Weisberg (Rel. Poultry Jour., 18 (1911), No. 4, pp. 596, 627, fig. 1).—An account of the origin and characteristics of a new general utility breed of fowls.

The principles of ostrich feeding, J. E. DuRoden (Agr. Jour. Brit. East Africa, 3 (1910), No. 3, pp. 233-240).—This article discusses wild and tame breeding stock, the characteristics of the perfect plume, selective breeding, and variability in progeny.

The influence of climate on oyster propagation at Barnegat, N. J., 1909, J. Nelson (New Jersey Stat. Rpt. 1909, pp. 225-266, pls. 5).—The factors influencing oyster propagation which were studied included temperature, rainfall, direction of winds and their force, the extent of the tides, and allied phenomena as they affect one another and as they are modified by local conditions, topography, character of the bottom, and situation of streams.

The range of the spawning season observed thus far extends from June 10 until October, but the principal periods are between June 14 and August 10. Both spawning and spating occurred in climaxes which coincided with warm waves. The effect of such waves was to warm the water, especially on shallow flats. The temperature effect was greater in proportion to the difference between it and the temperature previously experienced. Hence it is that oysters taken from the warmer southern waters and planted in the colder northern waters fail to propagate although well filled with spawn, and that northern oysters taken into more southern regions will spawn earlier than the natives. A cold period followed by warm weather has a greater effect than if the contrast was less marked, and when a cool period succeeds a warm spell it has a chilling effect, even though the temperature is as high as that which in a reverse case would have stimulated spawning. It is stated that there are probably other causes, yet to be discovered, that supplement this influence of temperature.

It is unknown why spawn floats for weeks while growing to the spating size and yet is not seen in the filtration of the water between the warm periods. "Particularly important is the discovery that the spawn emitted does not set as spat as early as has been hitherto believed by the best authorities. This discovery has two aspects, one of encouragement and one of discouragement. The encouraging side is that we can take advantage of the long period in which the fry is floating to get the culch ready to plant at the very best time and not have to trust to luck. There is also hope of finding out other useful facts about the setting of spat. On the other hand, the discouraging feature that grows out of this discovery is that it will be more difficult to breed oysters artificially than we had hitherto hoped."

Observations and experimental data on spawning, fertilizing, salinity, and filtration are reported and summarized in tables and charts. An alleged oyster disease was investigated and found to be due to a deposit of mud, which settled in a depression whenever easterly winds prevailed in the spring for a considerable length of time. A floating laboratory for further study of oyster propagation is illustrated and described.

On the composition of forage plants, L. Goelet (Jour. Soc. Agr. Brabant et Hainaut, 56 (1911), No. 22, pp. 271, 272).—Analyses are reported of clover, alfalfa, and prairie hays.

Stoffwechsel, n. ser., 6 (1911), No. 139, 140).—This deals with the chemical composition and the use of the soy bean and its by-products for feeding purposes.

The investigations of others on this subject are reviewed, and digestion experiments by the author are reported in which the coefficients of digestion in experiments with wethers were as follows: Soy-bean cake from which the oil had been removed by pressure, protein 92.8, fat 92.8, nitrogen-free extract 102.7, fiber 36.1 per cent; cake from which the oil had been extracted, protein 91.9, fat 67.6, nitrogen-free extract 105.4, fiber 30.3 per cent. Averaging these results with those obtained by other investigators it is estimated that in 100 lbs. of pressed soy-bean cake there are the following amounts of digestible nutrients: Protein 43.3, nitrogen 31.1, fat 6.9, fiber 4.4 lbs.; in the extracted cake, protein 48, nitrogen-free extract 34.6, fat 1.2, fiber 5.2 lbs.

A bibliography of the literature on the subject is appended.

Molasses and sugar foods for live stock, W. Goodwin (Jour. P. Agr. [London], 18 (1911), No. 2, pp. 97-106).—A summary of information on the value of molasses as a feed for live stock, based on the latest scientific investigations in different countries. The author warns stock feeders against paying a high price for molasses feeds when the absorbent material is peat or some other substance containing little or no nutritive material.

On oat-mill refuse feeds, N. Hansson (K. Landbr. Akad. Handl. och Tidskr., 50 (1911), No. 1, pp. 89-83).—Analyses of the various oat refuse feeds are given and their feeding value discussed. Attention is called to the varying composition of these feeds and to the necessity of obtaining guarantees for their maximum fiber contents, as well as for the minimum percentages of protein, fat, and carbohydrates which they contain.

Some condimental stock feeds (kraft-och hälsofoder), their composition and feeding value, N. Hansson (Meddel. Centralanst. Föröksv. Jordbruksområdet, 1911, No. 41, pp. 16).—The results of chemical and microscopical examinations of proprietary stock feeds and one sample of concentrated feeding phosphate are given. Farmers are warned against purchasing feeding stuffs composed of unknown mixtures and sold at high prices under fancy names on account of their medicinal qualities. “Above all it is in order to suspect all preparations sold at much higher prices than our best concentrated feeding stuffs. There are no mixed feeds that can have an appreciably higher value than these for healthy animals.”

Report of commercial feed stuffs, J. E. Halligan (Louisiana Stas. Feed Stuffs Rpt. 1909-10, pp. 120).—Analyses are reported of 9,381 samples of cottonseed meal, cottonseed feed, corn chops, hominy feeds, brewers’ grains, poultry feeds, alfalfa meal, molasses and other mixed feeds, and wheat, rice, and animal by-products.

Notice of judgment (U. S. Dept. Agr., Notice of Judgment 868, pp. 2).—This relates to the misbranding of proprietary feeds.

Public abattoirs: Their planning and the organization of their personnel, S. M. Doddington) Jour. Meat and Milk Hyg., 1 (1911), No. 5, pp. 266-274).—A consideration of the essential factors which should govern the construction, equipment, and arrangement of public abattoirs.

Some modern abattoirs and abattoir methods, A. Trimble (Jour. Meat and Milk Hyg., 1 (1911), Nos. 2, pp. 98-109; 4, pp. 207-219, figs. 12).—These articles contain the main facts of a report of a committee from Belfast, Ireland, which investigated the arrangement and equipment of slaughterhouses and methods of slaughtering as practiced in Rotterdam, Hamburg, Berlin, Dresden, Cologne, and Islington.
EXPERIMENT STATION RECORD.

DAIRY FARMING—DAIRYING.

Annals of dairying in Europe.—Dairy husbandry from prehistoric times, L. M. Douglas (Cream, Jour., 21 (1911), Nos. 23, pp. 1, 2, figs. 5; 24, pp. 1, 2, fig. 1; 22 (1911), Nos. 1, pp. 1, 2; 3, pp. 1, 2; 4, pp. 1, 2, fig. 1; 5, pp. 1, 2, figs. 6; 6, pp. 1, 10, 11, figs. 10; 7, p. 1; 8, pp. 12, 24, figs. 2; 9, pp. 9, 20, figs. 2).—The history of dairying from its beginnings with the early Hebrews, Greeks, and Romans up to the time of the introduction of modern methods as practiced in European countries is briefly reviewed.

Farm dairying, Laura Rose (Chicago, 1911, pp. XIV+298, pls. 29, figs. 37).—A practical work which treats of dairy husbandry and the manufacture of butter and cheese.

Bulletin of the International Federation of Dairying (Bul. Féd. Internat. Lait., 1911, No. 5, pp. 72, pls. 3).—This contains information relating to the affairs of the International Dairy Federation and other matters of general interest to those interested in the production and sale of dairy products.

Cow fodder, P. McConnell (Jour. New Zeal. Dept. Agr., 2 (1911), No. 4, pp. 212-214).—A study of the value of Bhuda kale, thousand-headed kale, and rape, as compared with other feeds for tiding cows over the dry season in New Zealand.

The Bhuda kale was the first to show the effects of drought. Rape was the only one of the three to be affected by clubroot. All 3 fodders gave a very pronounced unpleasant flavor to both milk and butter. Bhuda kale gave the highest average milk yield, but, on the other hand, yielded a much less weight per acre. Considering the good and bad points of all 3 fodders, the thousand-headed kale ranked highest, as it yielded a high average amount of milk and resisted drought and attacks of parasites.

When a change was made in the ration from these fodders to corn fodder there was an increase in the daily average milk yield of 2½ lbs. per cow, and the quality of the milk and flavor of the butter was improved. One acre of Japanese millet gave a yield of 22 tons of green fodder per acre, and on many farms it has taken the place of maize. Tares proved to be an excellent fodder, especially in the winter months.

A 4-year test of meadows, J. P. Beiler (Deut. Landw. Tierzucht, 15 (1911), Nos. 15, pp. 173-175, fig. 1; 16, pp. 185, 168).—In experiments with milch cows during the years 1905-1908, hay from fields fertilized with Thomas slag and kainit gave, even when the soil contained a good proportion of potash, larger yields and of superior chemical and botanical composition than hay which had received Thomas slag without kainit.

Milk production.—IV, Computing rations for dairy cows, O. F. Hunziker and O. E. Reed (Indiana Sta. Circ. 26, pp. 21).—This presents tables and data to encourage cow owners to give more attention to the feeding of their cows by being able to formulate rations.

Winter milk production, J. L. Duncan (Dept. Agr. and Tech. Instr. Ireland Jour., 11 (1910), No. 1, pp. 132-141).—A report of a 3-year experiment at the agricultural station of Clonakilty on the economics of winter dairying in the south of Ireland. The average yearly production per cow was 733 gal., at an average cost of 4½d. per gallon. The average fat content of the milk was 3.42 per cent.

[The college dairy herd], F. C. Minkler (New Jersey Stas. Rpt. 1909, pp. 56-76, pls. 7).—A general account is given of the management and records of the college dairy herd.

During the year ended November 30, 1908, the average yield of 24 cows was 8,857.7 lbs. of milk, containing 4.38 per cent of fat. The following year the
average yield for 31 cows was 8,561.1 lbs. of milk, containing 4.26 per cent of fat. The average cost of the feed for each cow per day was $33.3 cts. and per quart of milk 3.04 cts. The total cost of milk, including labor, was 4.16 cts. per quart when based on the cost of growing the feed consumed and 4.8 cts. when based on market prices of feed.

Milk records of twelve different breeds of cattle (Dent. Landw. Presse, 38 (1911), Nos. 36, pp. 418-420; 37, p. 431; 38, pp. 441, 442; 39, pp. 556, 557; 40, pp. 466, 467; fbg. 36).—This series of articles contains data of the milk production of 12 German breeds.

Further investigations on the influence of stimulating substances on milk secretion, G. Fingerling (Landw. Vers. Stat., 74 (1911), No. 3-5, pp. 163-182).—In continuation of earlier work (E. S. R., 22, p. 677), 3 goats were fed a mixture of appetizing foods composed of malt sprouts, starch, sesame cake, meadow hay, and salt. Larger yields were obtained with this ration than on a ration which contained the same amount of food material but consisting of less palatable foods, such as peanut oil, starch, gluten, feed lime, hay ash, and straw. When molasses was added to the latter ration the yield was increased, showing that the materials in the molasses have favorable effect on milk secretion outside of any digestible nutrients which they contain.

Analyses of feeds and feces and other data are included in the report.

Influence of watery feeds on the quantity and quality of milk, F. Tangl and A. Ziatschek (Landw. Vers. Stat., 74 (1911), No. 3-5, pp. 183-249).—In this investigation the rations of 10 cows were so changed from time to time as to contrast succulent feeds, or those containing a large percentage of water, such as pumpkins, roots, potatoes, and corn distillery slop, with a dry feed like alfalfa. Hay, barley, maize, and rape cake were fed to all groups, and in some cases straw and clover bran.

Taking the results as a whole, neither succulent rations nor the increased consumption of water had any effect on the yield or the composition of the milk. Generally a change to distillery slop, roots, or alfalfa increased the yield, whereas there was a slight decrease caused by pumpkins and a large decrease by pumpkins. A much smaller amount of water was drunk during the slop and pumpkin period than at other times.

It is concluded that the yield of milk is dependent upon the quality of the feed, as well as upon its starch value.

Analyses of milk and feeding stuffs are presented in tabular form.

On the influence of feeding stuffs on the composition of milk fat, A. Ziatscher (Landw. Vers. Stat., 74 (1911), No. 3-5, pp. 259-262).—As a result of a study made of the effect of the rations used in the above experiments on the nature of the milk fat, the following conclusions are drawn:

A ration consisting of feeds which have a high iodin number, such as maize, barley, bran, and rapeseed cake, causes a rise in the iodin number of the milk fat, but the Köttsdorf and Reichert-Meissl numbers are lowered. Roots and potatoes increased the volatile fatty acids in milk fat as compared with maize and rapeseed cake. Although the fat in the feeds influenced the composition of milk fat, rations composed of quite different feeding stuffs can produce the same amount of milk fat. Toward the end of the lactation period the saponification and Reichert-Meissl numbers of the milk fat were lowered, while there was a rise in the iodin number, the refractive index, and the melting point. After a change in feed the saponification and iodin numbers of the milk fat were quicker to change than the Reichert-Meissl number.

The relation between the fat of milk and the colostrum to the fat of the food and the body of the mother and embryo, A. Bone (Über die Beziehungen zwischen den Fetten der Milch und des Kolostrums zu den Fetten der Nahrung,
des mütterlichen und des kindlichen Körpers. *Inaug. Diss.*, Univ. Bern, 1909, pp. 43).—Analytical constants are reported of (1) the body fat of the fetus and young of man and domesticated animals, (2) the fat in milk and colostrum, and (3) milk fat as affected by age, breed, and feed. The properties of colostrum fat were found to lie between those of milk fat and body fat.

A bibliography is appended.
